no such complication. It would be remarkable that such a result might be obtained even though the external opening had been long delayed if they did not remember what occurred in the treatment of pulmonary abscesses. It was probable that some of the cases in which a permanent fistula remained were complicated with bronchiectasis. might not only survive but retain good health for years. He had seen several such cases and had attempted (unsuccessfully, however) to close the fistula. But some of them succumbed to complications after improving for a time. In those one should be on the look out for tubercle. He next considered a small class of cases which healed readily and rapidly and remained well for longer or shorter periodsmonths, or perhaps years—and then the trouble recurred, and perhaps not only once but on several occasions. No doubt a spicule of dead bone was sometimes the cause, or a ligature, or perhaps a minute piece of necrosed tissue, but one often failed to discover such a foreign body. One recurrence need cause but little anxiety, but a second or third should make one speak doubtfully. Sometimes the healing process came to a standstill because the drainage was imperfect or because the cavity was too large. The latter condition might be anticipated where no adhesions had formed, and especially where none existed between the base of the lung and the diaphragm or the inner surface and the mediastinum. Those most unpromising cases resulted from the rupture of a pulmonary infarct, a liver abscess, or something of that sort into a previously healthy pleura. The immediate outlook there was serious, as if not quickly opened the patient might die within a day or two. The ultimate prognosis was also grave, as the cavity was sometimes so large that it could not be closed by the most extensive thoracoplasty. Should the thoracoplasty succeed, the prospect was, he believed, as good as that of an empyema which had closed by natural processes. It should be observed that extensive thoracoplastics were not without their dangers, such as shock, septic absorption, and cerebral abscess. Tubercle was the commonest cause of the nonclosure of empyemata of moderate size; sometimes that was because a calcareous gland, or a calcareous plate, or a piece of necrosed bone was hidden away in the depths of the cavity; sometimes apparently it was simply because the tubercle bacillus was present. Perhaps others could say something about the influence of tuberculin injections on the prognosis. He regretted that he had as yet no valuable information to offer. Some tuberculous empyemata or empyemata in tuberculous subjects closed after incision. But though those good results were not uncommon, it was not safe to prognosticate too favourably for such people. It was fortunate, however, that one could honestly tell them, or at all events their friends, that a comparatively comfortable and possibly a prolonged life might be in store for them, and unnecessary to dwell upon the fact that an extension of the tuberculous process to other parts not infrequently occurred. Estlander's operation was, in his experience, risky and seldom successful in tuberculous cases, even if the cavity be small. Still, as it occasionally succeeded, one was sometimes tempted to offer the chance; but it was certainly not right to speak confidently about the Caries of the spine was not a common cause of empyema, and when the combination did occur the prognosis was certainly worse than that of uncomplicated Pott's But even those cases were sometimes remarkably With regard to bronchiectasis, he passed over bilateral cases because they seldom, if ever, admitted of surgical treatment. They had to deal with unilateral bronchiectasis depending sometimes on the temporary or permanent lodgment of foreign bodies, and sometimes on other preceding diseases of the lung or pleura. Mr. Godlee recited briefly a few cases, showing how long they might go on, and to what extent improvement might take place. He summarised his experiences thus: 1. That patients with considerable bronchiectasis, whether operated on or not, might live for a great many years in spite of the continuance of the expectoration. 2. That severe and recurrent hæmorrhage was a common symptom. But he had only known one patient die as a result of it, and that was an old man with a very septic state of things whose lung he had freely incised. 3. That in some cases, such as very localised ones or those caused by the inspiration of foreign bodies, drainage of the abscess might effect a cure, but more often attempts at surgery only led to temporary relief.

He had no personal experience of the removal of the affected portions of lung, but such operations were reported from Germany, and with a measure of success, and, it must be added, with an appreciable mortality. 4. The risks of operation were septic absorption, including cerebral abscess and hæmorrhage. It would be interesting to hear what was the chance of life in the purely medical cases. Of such he had seen a considerable number, but usually only once, and had had no means of following up their after-history. The late Dr. G. I. Schorstein gave the cause of death in 63 cases who were admitted to the Brompton Hospital between 1882 and 1904. That did not help much in the matter of prognosis, because he did not give the duration of the disease, and of course they had no account of those people who endured bronchiectasis—say, like gout—as one of the accidents of life and who did not come into hospital to die from it, and, in fact, perhaps died from old age or some other complaint. There were, however, three points of much interest. One was prepared to find that the largest number of deaths—17—were from broncho-pneumonia, but it was startling to see that 13 died from cerebral abscess and instructive that four died from hæmoptysis. In speaking of localised pulmonary abscess they were again not concerned with those cases which died outright, whether opened or not, such as some of those which occurred during an acute pneumonia or some secondary septic cases. Nor need they consider the ordinary tuberculous apical vomicæ. The point of interest was the after-history of such localised abscesses as arose in connexion with pneumonia, or embolism, or the bursting into the lung of abscesses from other parts, or the presence of foreign bodies and a very small number of tuberculous cases. He had only seen one basic tuberculous cavity close after incision. The others had benefited by operation only in so far as the expectoration was diminished. Otherwise the disease had followed its natural course. He had seen several cases where what were diagnosed as small pulmonary abscesses, which exploration failed to discover, were expectorated, and that was followed by apparently complete recovery. And he could produce the histories of several cases where, when a localised pulmonary abscess had been successfully reached, cure had followed, and the patient had remained well for many years. He believed, indeed, that such patients were no worse off than they were before. The cautious prognosticator would not forget that it was not only in the case of serous effusions, but also that of empyemas and pulmonary abscess that carcinoma and actinomycosis had to be thought of. As to actinomycosis, it was a fruitful cause of error, and nothing but great watchfulness would prevent mistakes, which not only endangered the chances of the patient but the reputation of the medical attendant. Perhaps he would be thought to be giving too hopeful an account of the probable future of patients after a pulmonary abscess. It was impossible to say that some cases of bronchiectasis following obscure pulmonary conditions might not depend upon such a cause, but he had no facts to offer pointing in that direction. He wished he could give any guide as to the likelihood of the occurrence of cerebral abscess, which so comparatively often stepped in to blast the most hopeful prospects. He had seen it occur in what appeared to be ordinary straightforward cases of empyema, in bronchiectasis both acute and chronic (but only after operation), in gangrene of the lung, and in several cases of abscesses of the lung caused by the bursting upwards of an abscess of the liver. In the valuable contribution to the subject by the late Dr. Schorstein above referred to, it was suggested that of all the diseases under discussion bronchiectasis was the most likely to be followed by cerebral abscess. One did not mention that bugbear in giving a prognosis, but it was a shadow in the background for those who had much to do with thoracic surgery, making them anxiously examine the pulse and temperature of any suppurating case who unexpectedly complained of a headache. Cerebral abscess was the end of all prognosis, and it might supervene after many years.

Dr. THEODORE WILLIAMS said that he had been a life insurance medical officer for 30 or 40 years, and with regard to old empyemata and cured pleurisies some of them had come before him in that capacity; they were rare, and as far as he could remember the custom had been that if there had been no signs or symptoms for some years they were

accepted at the ordinary rate. That was the plan in his own office, and, he believed, in some others also. But it must be clear that there had been no return of symptoms for some vears.

PATHOLOGICAL SECTION.

Presidential Address. - Rhabdomyoma of Urinary Bladder.

A MEETING of this section was held on Oct. 19th. Dr. F. W. Mott, the President, being in the chair.

The PRESIDENT took for the subject of his address the present position of the neuron doctrine in relation to neuropathology. He pointed out that a neuron consisted of a nerve cell together with all its processes, including the protoplasmic processes or dendrons, and the single axis-cylinder process with its cone of origin, its collaterals or side branches, and its terminal arborisation. The neuron theory was that the nervous system consisted of innumerable such anatomically independent nervous units in contiguity but not in continuity. There was interlacing of the processes but no network. The nervous units were genetically and trophically independent cellular organisms arranged in functionally correlated systems, communities, and constellations. experiments of Harrison showed that ganglion cells could form nerve fibres without the aid of sheath cells, and the same observer also found that nerves separated from their cells of origin degenerated rapidly and no signs of regeneration were observed. The embryological basis of the neuron doctrine had been established beyond dispute. The formation of connexions of one neuron with another by fibrils and the passage of fibrils from one nerve cell through another nerve cell were matters of detail which in no way shook the fundamental principle of the neuron concept. The anatomical observations of Cajal and others regarding the genetic independence of the neuron had been fully confirmed by the researches of Harrison. Experimental and clinico-anatomical observations indicated that the sheath cell played an important part in regeneration after injury of the axon. The trophic activity of the spinal motor neurons was in all probability independent of stimulus arriving from other neurons. They possessed, indeed, a trophic autonomy; the observations of Harrison supported that idea, and it, moreover, accorded with the neuron doctrine of genetic and trophic independence. Direct injury of any part of the neuron caused changes but not injury to neurons with which it was functionally but not nutritionally correlated. If sections were made of the junction of the central and peripheral ends at successive periods of time three stages could be seen: first, the sprouting of large numbers of new fibres from the central cut axon; secondly, the penetration of the bridge of young vascular connective tissue joining the cut ends by the young nerve fibres; and thirdly, the penetration and growth downwards of these young fibres between the proliferated sheath cells of the peripheral portion. There could be no doubt that the new nerve fibres depended upon an outgrowth from the central cut ends of the axon. The President concluded his address by saying he would rest content if he had satisfied the members of the section that the neuron doctrine pronounced dead only a few years ago now rested on a surer basis than it ever did.

Mr. S. G. SHATTOCK exhibited the bladder of a male child, aged 2 years, from the mucous membrane of which many polypi projected. Histologically they consisted almost solely of striated muscle fibre, in all the normal stages of development from large multinucleated sarcoblasts. In discussing this unusual site of striped muscle Mr. Shattock adopted the view that heteroplasia in the case of tumours meant heterotopia, or the displacement of embryonic elements from a normal to an abnormal position. Certain of the striated fibres of the external sphincter vesices (Henle) lay deeply in the substance of the anterior or upper portion of the prostate, Henle's description in this respect having been recently fully confirmed by Mr. C. S. Wallace. And it was from vagrant sarcoblasts that the cells from which the striated fibres in the mucous and submucous coats probably developed. In favour of this view was the fact that the tumours were confined to the neck of the bladder, and they were almost certainly congenital.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION.

Teaching of Therapeutics in the Hospital Ward.

A MEETING of this section was held on Oct. 5th, Professor A. R. CUSHNY, F.R.S., the President, being in the chair.

Sir T. CLIFFORD ALLBUTT opened a discussion on the Teaching of Therapeutics in the Hospital Ward. He said that medical men must be pioneers, they could not afford always to wait for the pharmacologists; but there must be a mutual watchfulness of each other. Much that we knew to-day to be good came from empirical knowledge; this is still going on, but our empiricism must be of the best, the knowledge of experience. He selected three examples of methods of treatment which had stood the test of modern research, but which came originally from folk-medicine, viz., digitalis; vaccination, which to-day had wonderfully expanded in other directions; and poultices, which, after suffering a period of abuse, were, through the work of Bier, seen to be fundamentally reasonable. The student must be assured that apart from pharmacological proof, there was a large tradition of empirical knowledge of great provisional service. He should be told that such and such are the means found useful in clinical experience, whether they could be scientifically explained or not. They were to go to the bedside as artists to do what they could for the patient with such lights as they had. Finally, the student must be told he has to deal with living realities. He must be (1) assured he must be no sceptic, or he would endanger his own resourcefulness; (2) given a clear idea of the vis medicatrix nature; (3) warned against the danger of the overuse of drugs, and shown how closely therapeutics depend upon prognosis.

Professor W. OSLER gave an account of the methods adopted at the John Hopkins University, laying stress on the

practical advantage thereof.

Dr. HARRINGTON SAINSBURY thought that there should be more careful teaching of the history of therapeutics and of

the present-day acceptance.

Dr. J. CALVERT said that there was a lamentable ignorance of incompatibility and of the ordinary simple practical methods which should all be systematically taught in the

Dr. R. HUTCHISON relied more on teaching the student to be a sound diagnostician than a pharmacologist, and suggested that the time was ripe for some uniform agreement on the main lines of treatment to be adopted in certain well-known diseases, such as gastric ulcer.

Professor W. E. DIXON insisted on the advantage to the student of a sound pharmacological knowledge; and he pointed out the rational value of administering alkaloids the strength and action of which were accurately known.

Dr. A. P. BEDDARD thought it was impossible really to

teach therapeutics in the wards.

Sir DYCE DUCKWORTH emphasised the necessity of imparting practical instruction to the student, such as in the giving of enemata and hypodermic injections. He deplored the multitude of new so-called remedies, many coming from abroad.

Dr. J. HACKNEY said that the student should be taught how to manage a practice, to keep books, and be given a general idea of ordinary routine work.

The PRESIDENT closed the discussion with a few remarks.

THE SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

Slooping Sickness.

A MEETING of this society was held on Oct. 15th, Professor RONALD Ross, the President, being in the chair.

Dr. A. G. BAGSHAWE delivered an address on Recent Advances in our Knowledge of Sleeping Sickness, which is

printed on p. 1193 of this issue of The LANCET.

Dr. D. N. NABARRO said he was glad to see that the importance of the examination of the blood in the diagnosis of sleeping sickness was coming to the fore, because he was convinced that examination of the blood properly carried out was of great value.

Dr. A. BREINL (Liverpool) pointed out that too much reliance ought not to be placed on auto-agglutination. Dr.

Breinl also demonstrated sections from the brain of a monkey that died after infection with the Trypanosoma gambiense.

Dr. J. D. Thomson spoke of the value of ethyl antimony tartrate in the treatment of sleeping sickness.

Dr. G. C. Low said that in regard to enlargement of the glands attention must be paid to the part played by syphilis. Dr. F. M. SANDWITH gave details of some cases of sleeping sickness which he had seen last April in the infectious wards attached to the Pasteur Institute, and he understood that no ill effect had followed the use of atoxyl.

Dr. L. W. Sambon made some remarks on the etiology of the disease and discussed measures of prevention.

Mr. L. G. HILL described some early cases seen at the London Hospital, which the PRESIDENT said that he had seen also

Dr. C. F. HARFORD asked if the period of incubation was definitely established.

Dr. BAGSHAWE, in the course of his reply, said that it was fairly certain that the period of incubation was not more than 10 days, and it might be less than that period of time.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCO-LOGICAL SOCIETY.—A meeting of this society was held in Liverpool on Oct. 15th, Dr. J. W. Martin (Sheffield), the President, being in the chair.—Dr. A. J. Wallace (Liverpool) showed an extreme example of Hydrocephalus and also a Uterus and Vagina removed for Carcinoma of the Cervix, extending superficially over the entire anterior vaginal wall. The uterus was freely moveable and there was no infiltration of the parametric tissues. The vagina was first separated from below, and its lower end invaginated and closed by a double row of sutures. The operation was completed by the abdomen, an ordinary pelvic dissection being performed. The pelvic glands on the left side were enlarged and were freely removed; those on the right were greatly enlarged and too intimately adherent to the iliac vessels to justify removal.—Dr. J. E. Gemmell (Liverpool) showed a good example of a rare feetal monster-Symelus. - Miss Frances Ivens, M.S. (Liverpool), read the notes of five cases of Tuberculous Salpingo-ovaritis. In four the disease was apparently primary in the tubes; in the fifth there was an associated bone lesion. Dysmenorrhœa was the only symptom common to all. Dysuria occurred in four cases and menorrhagia in three. The ages varied from 20 to 36 years. In no case was the uterus removed, though both tubes were extirpated in each instance. A portion of ovary was left in all but one case. In all there has been an immediate and maintained good result, with gain in weight and freedom from pain. In one tuberculous peritonitis developed but subsided with tuberculin treatment.—Dr. Arnold W. W. Lea (Manchester) read a paper on Gastric Ulcer as a Cause of Pelvic Peritonitis, with notes of three cases. Chronic adhesive pelvic peritonitis, with more or less disorganisation of the uterine appendages, was found on abdominal section in each case. No evidence of the usual causes of pelvic peritonitis could be obtained. On the other hand, there was in each instance a history of severe chronic gastric dyspepsia, with an illness suggestive of a leaking gastric ulcer, from which the patient had recovered without an operation. -Dr. H. Leith Murray (Liverpool) read a paper on the Antiautolytic Action of Blood Serum and its relation to Hyaline Degeneration in Uterine Fibroids. He said that small pieces of a fibroid incubated in serum very soon developed distinct hyaline change limited to the connective tissue. Muscle fibres took a purely passive part in the process. The hyaline appearance produced resembled hyaline degeneration occurring naturally, both in general microscopical examination and in staining peculiarities. The clear fluid cavities in cedematous fibroids did not result from thinning out of surrounding hyaline material, as Kelly and Cullen asserted, but the fluid in them was directly responsible for that change and could produce it in vitro.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on Oct. 15th, at which Mr. C. Gordon Watson, the new President, delivered an address on Recent Advances in Rectal Surgery. He said that radical operations for the extirpation of cancer of the tongue, larynx, and breast, with the glands involved, have long been established, but it is only in the last two or three years that surgeons have begun to regard the rectum as amenable to a similar form of treatment. The explanation seems to depend partly

on the failure to recognise the importance of the lymphatics in the pelvis in relation to the upward extension of the disease, partly to a wholesome fear of operating through the peritoneal cavity, but chiefly to the deplorable delay in diagnosis, a delay for which the patient is not always to blame. We now have a valuable aid to diagnosis in the sigmoidoscope, which enables us to examine in the great majority of cases the lower 12 inches of the bowel. The abdomino-perineal method of excision of the rectum will be the operation of the future. It aims at removing not only the diseased bowel but also the lymphatic glands in the hollowof the sacrum and the lymphatic vessels in the mesentery of the pelvic colon, up to the bifurcation of the left common iliac artery; in fact, it aims at dealing with the rectum in the same way that the Wertheim operation deals with cancer of the uterus. Ano-rectal ulceration is the term given by Wallis to a condition constantly found in the lining membrane of that part of the bowel which lies between the anus and the internal sphincter. lesion is a pathological condition which is the initial cause of many of the ordinary rectal ailments. It is a cause of genuine pruritus ani and of fissure, the chief cause of all ischio-rectal, submucous, and subtegmentary abscesses, and as a natural sequence the cause of all fistules, which are the residue of these abscesses, and finally it is the cause of those distressing cases of infective rectal ulceration which cause so much pain and misery and are so intractable to treatment. In the great majority of inveterate cases of pruritus ani a shallow ulcer will be found within the anal canal situated between the two sphincters, usually posteriorly, and they can usually be cared by the application of the actual cautery or by zinc sulphate cataphoresis.

HUNTERIAN SOCIETY.—A meeting of this society was held on Oct. 13th, when Dr. Sidney H. C. Martin delivered the first Hunterian lecture of the present session on "Certain Infective Processes in the Intestine: their Effects and Treatment." The lecturer classified bacteria having their habitat in the intestine into three groups: (1) endogenous, bacillus coli communis and streptococcus fæcalis; (2) exogenous, such as typhoid; and (3) putrefactive. The last class when they developed led to serious pathological results. The rôle of the bacillus coli was to counteract putrefactive bacteria; the bacillus coli and the bacillus acidi lactici prevented putrefaction in boiled milk. When introduced into the tissues the bacillus coli became pathogenic, its chemical product being an endotoxin, which produced a profound effect on the bodily temperature (lowering it) and nutrition, causing wasting. A septicemia which sometimes followed enteric fever and cholera was due to bacillus coli. The bacillus coli tended to produce illness irregular in type and tending to get well and relapse; it acted by side infection, producing disease in the gall-bladder, pancreas, or appendix, had a direct effect on the mucous membrane, producing such conditions as mucous and ulcerative colitis, or passing into the blood stream caused pyelitis, cystitis, thrombosis, meningitis, and infective endocarditis. In his remarks on treatment the lecturer pointed out that vaccination by the bacillus coli did not always cure but produced remarkable results in some cases and instanced two cases of thrombosis, in which the effect had been markedly good. He considered big doses dangerous and recommended from 1 to 4 millions of the dead bacilli per dose. A toxic dose produced definite local reaction and swelling.

Overcrowding in Lambeth. — A case recently came before the notice of the Lambeth board of guardians, the medical significance of which is considerable. The occasion was the application for outdoor relief by a family of three, consisting of the parents and a child, aged seven years, all of whom lived in one back room of insufficient size. The wife was in an advanced state of pregnancy, while the husband had been certified to be suffering from chronic phthisis. Despite the very strongly worded appeal of the chairman of the board to the man to go into the infirmary and not endanger his wife's health by continuing to live in the same room with her, the applicant refused to leave his wife, saying he could eara a little, and eventually the board granted 3s. in money and 3s. in food per week relief.

Bebiews and Notices of Books.

A System of Medicine by Eminent Authorities in Great Britain, the United States, and the Continent. Edited by WILLIAM OSLER, M.D. Oxon., F.R.S., Regius Professor of Medicine in the University of Oxford; assisted by THOMAS McCrae, M.D., F.R.C.P. Lond., Associate Professor of Medicine and Clinical Therapeutics in the Johns Hopkins University, Baltimore. Vol. VI. London: Henry Frowde and Hodder and Stoughton. 1909. Pp. 799. Price 30s. net per volume, or 24s. net per volume to subscribers.

In this volume a variety of conditions are describednamely, diseases of the urinary system, diseases of the ductless glands, diseases of the muscles, vaso-motor and trophic disorders, and diseases "of obscure origin." The principles of life insurance are also discussed from the medical stand-

Part I. is concerned with Diseases of the Urinary System. "An Introduction to the Diseases of the Kidney" is written by Dr. J. McCrae (Montreal), who refers to certain points in the physiology and pathology of that organ. The same author also considers the malformations and circulatory disturbances of the kidney, including under the latter title anæmia, hyperæmia, and thrombosis of the renal vessels and infarcts of the kidney.

Dr. A. E. Garrod (London) contributes an interesting article on Anomalies of Urinary Excretion. In addition to entering upon an able discussion on the various aspects of albuminuria, pyuria, phosphaturia, and other commonly occurring phenomena, he also describes more rare conditions, such as hæmatoporphyrinuria, alkaptonuria, and cystinuria. Dr. Garrod is also responsible for the chapter on uramia. He is forced to the unsatisfactory conclusion that, in spite of the large amount of patient research which has been expended upon the problem of the nature of urzemia, from the days of Bright and Addison down to the present, no solution yet proposed has met with general acceptance, and the cause of the condition still remains unknown. He passes in review the various theories that have been suggested, drawing attention to one of the most recent-namely, the production of nephrolysins, a pro position which has been advocated by Ascoli and others. It has been shown that just as when bacteria find their way into the animal organism, substances antagonistic to them are produced, so also when cells of a particular organ are injected under the skin, or into the peritoneal cavity, substances antagonistic to the special cells are found in the organism. Some of these cytolysins have been carefully studied, but the nephrolysins have not been so generally recognised. When broken-up renal substance is injected into animals, substances are found in the serum of the animals so treated which exert a destructive action upon the renal cells of other animals. When injected into a second animal such a serum sets up a nephritis and causes albuminuria. It has been suggested that the tendency to chronicity in renal diseases is due to the establishment of a vicious circle, and that the nephrolysins formed as a result of the renal lesions aggravate the morbid condition in the kidneys. Ascoli, and those who think with him, believe that the phenomena of uramia may result from the action of these bodies upon the nerve centres.

The subject of nephritis occupies five chapters, all having been written by Dr. J. B. Herrick (Chicago). We would especially draw attention to the remarks on the treatment of chronic interstitial nephritis. Dr. Herrick takes a moderate, common-sense view of the diet which is most suitable for patients suffering from this affection. After referring to the various views which have from time to time belongs. We consider his suggestion cound. For full

been expressed as regards drinking a large amount of liquid or the reverse, the value of an entirely milk diet and the effect of "red meats," he says: "The dietetic treatment may be summed up in a few words by saying that the diet must be a mixed diet from which all seasoned, spiced foods and alcohol are excluded; meat and other proteids are to be taken in moderation or small amounts; cereals, vegetables, and fruits freely; the sweets sparingly. Milk is allowed freely, but neither it nor water is to be taken in excess for the supposed benefit that is to come from flushing out the kidneys." This opinion is in accord with that held by many of the leading authorities. In commenting upon the operative treatment of chronic interstitial nephritis (decapsulation of, or incision into, the kidney) Dr. Herrick says that while in individual cases operation may perhaps be justified, an operation upon every case of nephritis is to be condemned; convincing statistics are not yet to hand to justify any statement that a surgical cure has been wrought of a disease of the character of chronic nephritis. Other diseases of the urinary tract which are described are: The Bacteriology of the Infections of the Urinary Tract and Urinary Findings in these Conditions; Pyogenic Infections of the Kidney, Ureter, and Perirenal Tissues; and Tuberculosis of the Kidney, by Dr. T. R. Brown (Baltimore); Tumours of the Kidney; Urinary Lithiasis, Renal and Ureteral Calculi; and Genito-urinary Diagnosis and Diseases of the Prostate, by Dr. H. H. Young (Baltimore).

The second part of the work deals with Diseases of the Ductless Glands. The writer of the four chapters on this subject is Dr. G. Dock (professor of the theory and practice of medicine, Tulane University of Louisiana). Diseases of the adrenal glands are first described. The chromaffin tissue and its relation to disorders of the gland, to which a considerable amount of attention has recently been drawn, are discussed, but Dr. Dock considers that the investigations conducted more especially by French observers are as yet too immature to warrant any definite conclusions being drawn. A good account is given of Addison's disease, and 'adrenal therapy" is touched upon. The author maintains that the use of adrenal preparations in this condition is legitimate, but they should not be given to the exclusion of symptomatic treatment. They are more promising in the early stages and must be used with extreme care in advanced cases, but even in the latter are permissible. In the chapter on diseases of the thyroid gland reference is made to parathyroid lesions. most important result of such lesions is tetany, or perhaps it would be more accurate to say post-operative tetany. MacCallum's experiments to attempt to explain the pathology of tetany are quoted, and it is suggested that the same theory can be applied to non-operative tetany. His results indicate the existence, in animals deprived of the parathyroids, of a poison which combines with certain cells in the central nervous system. A full description is given of exophthalmic goitre, the surgical treatment receiving favourable comment. Cretinism, myxcedema, and acromegaly are

Part III. is devoted to Diseases of Obscure Causation. These include Hodgkin's Disease, by Dr. W. T. Longcope (Philadelphia); Arthritis Deformans, by Dr. T. McCrae; Osteomalacia, by Dr. Dock; and Astasia-abasia and Adiposis Dolorosa, by Dr. J. McCarthy (Philadelphia). The article on arthritis deformans will well repay perusal. author considers that while an exact classification is difficult it seems best to discuss the clinical features under the various forms, always bearing in mind that there are not invariably clear-cut distinctions between them, and that it may not be easy to say exactly to which class a given patient

details we can only refer our readers to the original, but the following is an outline of the classification adopted: 1. Periarticular form. This is the most frequent, and comprises the cases sometimes described as "rheumatoid arthritis." The changes are most marked in the synovial membrane and perarticular tissues. The cartilage is also affected in many cases, but the damage is rarely extreme; whatever change occurs in the bone or cartilage is apparently secondary. 2. Atrophic form. This is much the least frequent in occurrence, and is in many ways the most serious as regards outlook. The most marked anatomical change consists in the atrophy of the bone, which may be very advanced. The progress in some cases is extremely rapid, and they might almost be described as fulminating. 3. Hypertrophic form (osteo-arthritis). In this the changes are more especially in the cartilage and bone, and very varying degrees of involvement are found, both as regards the amount of change in the cartilage and the extent of bone formation. The form is usually polyarticular, and apparently may come on at any age, but the majority of patients are older at the time of onset than those belonging to the peri-articular form. 4. Some of the forms of the so-called "infectious" arthritis. This group may pass over into arthritis deformans, and it is difficult to know where to draw the line. The frequent occurrence of arthritis with or after many acute infections has to be always remembered.

In Part IV. the diseases of the muscles are considered: myositis, Thomsen's disease, and myotonia congenita, by Dr. W. R. Steiner (Hartford, Conn.), and myasthenia gravis, paramyoclonus multiplex and periodic paralysis by Dr. D. J. McCarthy. All these contributions are carefully done.

In Part V. a description is given of vaso-motor and trophic disorders. Raynaud's disease, angioneurotic œdema, Quincke's disease, diffuse scleroderma, and erythromelalgia are described by Professor Osler. A comprehensive account is given of the symptomatology of Raynaud's disease, and some excellent reproductions of photographs enable the reader to obtain a good idea of the principal changes observed in the feet and hands. The differential diagnosis is also discussed in an instructive manner. The various forms of local necrosis which have to be distinguished are considered separately, the more important being grouped under four headingsviz., organic disease of the nervous system, obliterative arteritis, post-febrile necrosis, and multiple neurotic skin gangrene. Dr. C. P. Emerson (Clifton Springs Sanatorium) describes the following conditions: achondroplasia, hypertrophic pulmonary osteo-arthropathy, Paget's disease, osteogenesis imperfecta, osteopsathyrosis, leontiasis ossea, microcephalus and facial hemiatrophy.

The last part of the work deals with the medical aspects of life assurance; it is written by Dr. C. L. Greene, professor of medicine in the University of Minnesota. As is natural, Dr. Greene bases his remarks mainly on the results obtained by the American insurance companies, and we do not think that all which he has to say will be endorsed on this side of the Atlantic. We cannot agree, for example, with his remark that life insurance companies are constantly accepting men in the active stages of tuberculosis. Careful inquiry into the history of the applicant, combined with physical examination, should reduce such a risk to a minimum, but prolonged and scientific investigation by a medical man should command a proper fee, a fact which some life assurance companies will not recognise.

Professor Osler and Dr. McCrae may again be congratulated on having issued a most interesting volume, which fully maintains the high standard of its predecessors. The subjects considered in it are of widespread interest, and the various contributions are of great practical value.

Pratique de la Chirurgie Antiseptique; Leçons Professées à l'Hôtel-Dieu. (The Practice of Antiseptic Surgery.) Par le Docteur JUST LUCAS-CHAMPIONNIÈRE, Chirurgien Honoraire de l'Hôtel Dieu, Membre de l'Académie de Médecine, Membre du Conseil d'Hygiène et de Salubrité du Département de la Seine. Avec un portrait de Lord Lister. Paris: G. Steinheil. 1909. Pp. 463. Price 8 fr.

Dr. Lucas-Championnière was the first in France to employ the methods of Lister, and it was in 1874 that the opportunity came. For a few weeks in that year he undertook the work of Panas at the Lariboisière Hospital, and the wards in which his cases were placed were some of the most crowded and most infected wards of the hospital, for, he tells us, there were many patients dying from erysipelas and other septic conditions, and during the whole year no case of amputation had recovered. He determined to employ the antiseptic method and to follow Lister's teaching in all particulars, though he had to provide the dressings at his own expense. He took over the wards on Nov. 19th, 1874, and the next day he operated on a strangulated hernia and performed an amputation at the shoulder, while on the following day he trephined a patient who was comatose and had epileptiform seizures. All these cases recovered, and from that time to the present he has employed and taught antiseptic surgery. The book before us is an exposition of the methods he has used, and it is of great interest and importance in these days when what is called aseptic surgery is very extensively practised and when it is not rare to find that a little good-natured contempt is cast on antiseptic methods. As we have many times pointed out, the differences between the antiseptic and aseptic methods are much less important than many appear to think; but whatever differences there may be the methods employed by Lord Lister, and described in this work by Dr. Lucas-Championnière, are well able to hold their own. During the Franco-German war Dr. Lucas-Championnière acted as surgeon to an ambulance and he wished to take with him some carbolic acid which he had obtained, but his senior objected and it was not used. This little medical footnote to history shows that the introduction of the antiseptic method was as slow in France as in many parts of England. We have derived much pleasure from reading this volume, and we recommend it to all those who wish to have a full account of the best practice of antiseptic surgery.

Électrothérapie. By Professor T. NOGIER, Lyons. With 251 illustrations in the text. Paris: J. B. Baillière et Fils. 1909. Pp. 528. Price 10 francs.

This is the first volume of a series of books on physictherapy which are to appear under the editorship of M. Gilbert and M. Carnot. In reading the work we have been reminded of a similar book by Dr. Guilliminot which we reviewed some time ago in these pages. We do not suggest plagiarism in any way; we merely note the coincidences in style and method of experimenting and reasoning. Professor Nogier's work is divided into four parts. The first of these relates to apparatus and its management, and the second to electro-physiology, in the course of which a number of interesting points are discussed and then demonstrated by means of experiments. In the second section the action of the ordinary galvanic and faradic currents on nerve and muscle is given, as well as that of high-frequency currents on nutrition, while the author enters into the questions of cataphoresis and the induction of so-called electric sleep. The third section on electrodiagnosis is very well written and forms a valuable résumé of the present state of our knowledge on this subject. The last section of the book, that on electro-therapeutics, is the largest and most important, taking up about one-half of the whole volume. The author includes only those diseases

which are, as a rule, either cured or greatly benefited by electrical treatment. In the treatment of hemiplegia he advises that galvanisation of the brain and faradisation of the affected muscles should be commenced one month after the occurrence of the primary lesion in order to stimulate the repair of the cerebral injury and to obviate atrophy of the affected muscles. As has been shown by Leduc and practised by others in this country, galvanisation of the brain is safe so long as we avoid any sudden variation in the magnitude of the current. In infantile paralysis the author advises employment of slow rhythmic currents. His chapter on the various forms of neuritis is very complete, and here he lays stress on the importance of a careful electro-diagnosis as a preliminary to electrical treatment. A novel method of treating some forms of facial neuralgia is described in which the active electrode consists of a glass cannula containing a silver wire which is connected to the positive pole. The cannula is supplied with warm water from a douche tank. This is applied inside the nostril or mouth, the current reaching the mucous membrane through the water. In this way high current densities can be employed without risk of producing an electrolytic burn and the method has given very good results.

The section on diseases of the skin is fairly comprehensive, but the author appears to attach but little importance to treatment by X rays, radium, or ultra-violet light. He treats lupus erythematosus by a sort of modified fulguration which in spite of its painfulness he prefers to the X rays or Finsen light.

We think that Professor Nogier has written an extremely good book, one which forms a worthy addition to any medical library that has pretensions to being up to date and inclusive.

The Blood in Health and Disease. By R. J. M. BUCHANAN, M.D. Vict. and Liverp., F.R.C.P. Lond., Professor of Forensic Medicine in the University of Liverpool, Honorary Physician to Out-Patients, Liverpool Royal Infirmary. London: Henry Frowde, Oxford University Press; Hodder and Stoughton. 1909. Pp. 318. Price 12s. 6d. net.

The study of hæmatology and its application to clinical medicine and surgery have made great advances and proved to be of considerable utility during recent years. The full value of the examination of the blood and the conclusions to be drawn from the results have not yet been completely determined, but enough has been demonstrated to prove that in certain conditions a differential "count" of the erythrocytes and leucocytes yields information of great worth both as regards diagnosis and prognosis. The technique necessary to carry out the various processes is in some instances an involved one, and the morbid conditions that may be indicated are numerous. Consequently a trustworthy work devoted to a consideration of the blood in health and disease, containing the most recent researches on the subject, is to be welcomed, and such a book is now before us.

After a brief review of the characters of normal bloodthe methods of estimating the amount of hæmoglobin are discussed and the various forms of hæmoglobinometers are described. A chapter is next devoted to the less important procedures which are sometimes employed in connexion with the examination of the blood, such as the use of the spectroscope, the coagulation time, the estimation of the calcium salts and of the alkalinity of the blood and its specific The manner in which the opsonic index is estimated also receives attention. The methods and instruments which are employed in enumerating the erythrocytes and leucocytes are well described, and numerous hints are given which will be found of value by practitioners and students. Reference is also made to the enumeration of blood platelets, directions are likewise

given for the preparation of specimens for microscopical examination, while the composition of the principal stains employed is duly set forth.

The chapter dealing with the morphology of the erythro, cytes, and with their physiological and pathological variations in number and appearance, will be found full of interest, the various facts being commented on in a manner that at once attracts the attention of the reader. Particular importance must be attached to the chapters devoted to a consideration of the leucocytes. Of all the problems associated with the study of hæmatology, the changes in and varying proportions of the different forms of the white cells are the most difficult to follow and to understand. Dr. Buchanan treats the subject in a thorough and painstaking manner. The student is likely to be bewildered at first with the varieties of leucocytes which may be met with in the blood, more particularly as more than one name has been given by different observers to each of the forms. The classification here given, however, will be found simple and easy of comprehension. The significance to be attached to the presence of lymphocytes, eosinophiles, myelocytes, and so on, is clearly laid down, and the blood changes which occur in association with special diseases are carefully described.

The value of the work is considerably increased by a number of excellent coloured plates. These have been drawn with a view to providing a faithful atlas of the principal morphological changes which are to be found in abnormal blood states. They are beautifully produced and a full description accompanies each one. We were very favourably impressed with this book and can recommend it to those of our readers who are interested in the subject and who wish to supplement their knowledge both in the practice and theory of the study of the blood.

LIBRARY TABLE.

Masques and Phases. By ROBERT Ross. London: A. L. Humphreys. 1909. Pp. 315. Price 5s.—The ingenious Mr. Robert Burton in his wonderful Anatomy of Melancholy quotes a saying of Marsilius Ficinus, who was both priest and physician, of which we have been reminded in reading Mr. Ross's book. The saying occurs in a letter to a group of his friends and is as follows: "Iterum precor et obtestor, vivite laeti; illud quod cor urit, neglegite. Haec autem non tam ut sacerdos, amici, mando vobis, quam ut medicus; nam absque hac unâ tanquam medicinarum vitâ, medicinae omnes ad vitam producendam adhibitae moriuntur: vivite laeti." Michael Finsbury gave similar counsel, and Mr. Ross's book teems with what that admirable solicitor called "judicious levity." The essays are full of the best kind of fooling mixed with sound common sense and an intimate knowledge of literature and art. First we have an excellent short story about an archæologist, a blackmailer, and a forged manuscript, and other chapters are reminiscent of that unworthy follower of Psalmanazar—namely, Shapira. "The Eleventh Muse," "A Mislaid Poet," and "The Elethian Muse" deal with banalities in verse and prose, and the extract from Baedeker's Southern France, 1891 edition, which is given in the lastnamed, is pure joy. We are sincerely grateful also to Mr. Ross for recalling to our mind the immortal passage about the Roman Catholic church from that instructive work of the "fifties," "Near Home." More serious essays are a sympathetic biography of that unfortunate genius Simeon Solomon, and a retrospective view of Aubrey Beardsley. "Swinblake" can amuse but few people, it is too allusive, but those who take the allusions will be rewarded. The last section of the book is taken up by a brilliant lecture entitled "There is No Decay," delivered at Liverpool in 1908. We

commented upon this optimistic address soon after its delivery, and on re-reading it we again find its message true and inspiriting. We thank Mr. Ross for his little book, but we hope that in future writings he will allow himself to be somewhat simpler in his treatment. He demands from his readers always an intimate knowledge of things about which he should be informing them.

Elementary Physiology for Teachers and Others. W. B. DRUMMOND, M.B., C.M. Edin., F.R.C.P. Edin. With 80 illustrations. London: Edward Arnold. 1909. Pp. 198. Price 2s. 6d.—Dr. Drummond has essayed a difficult task. As hygiene now holds an important place in the curriculum of students in training as teachers, and as a sound hygiene must be based on physiology, this little book was written to meet the needs of those in, or about to enter, the teaching profession and not as a manual either of hygiene or physiology. Special attention is paid to the peculiarities of childhood, and a rather full account of the physiology of bodily exercise and of the anatomy of the bones, joints, and muscles is given. The writer has recognised that what is wanted is not a knowledge of the minute structure of a muscle, or even its origin or insertion, but rather how a muscle or a series of muscles may act and work in unison to produce a particular movement, and how the muscles are coördinated to this end by the central nervous system. The nervous system and sense organs receive special attention, though of course the work is quite of an elementary character. All the statements cannot pass unquestioned; for instance, under the head of the Chemical Composition of the Body we find the statement that "sodium chloride, or common salt, is the most abundant mineral salt." The microscopical illustrations are rather apt to mislead, no magnification being stated. The smooth muscle cell figured on p. 73 is longer, broader, and far more imposing than its cross-striated neighbour. It would not be difficult to find other points in the book to criticise, but we recognise that the need to say just enough, and only just enough, made this a very difficult book to write. We think that it will prove useful both to the teacher and to the student preparing himself to become a teacher. It seems to meet the elementary requirements of both in a readable form.

Aew Inbentions.

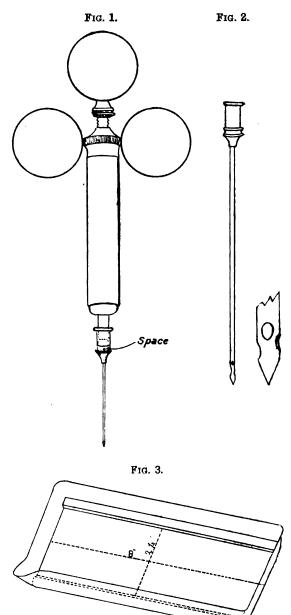

APPLIANCES FOR CLINICAL PATHOLOGY.

THE three pieces of apparatus which are described below have been devised during the work on human trypanosomiasis, carried out by the expeditions and in the laboratories of the Liverpool School of Tropical Medicine. They have all been used and have been found to fulfil the purposes for which they are intended. The syringe and lumbar puncture needle were supplied by Alexander and Fowler, the staining dish by Baird and Tatlock.

Fig. 1. Syringe for gland puncture.—This syringe was designed to fill the requirements of a syringe intended for use in the diagnosis of human trypanosomiasis by gland puncture. The finger rings were fitted in order that this manceuvre might be done by the operator without assistance. The space, indicated by the illustration, in the head of the needle below the nipple of the syringe has been provided in order that the drop of gland juice obtained by puncture shall be detained there and not drawn up into the syringe.

Fig. 2. A needle for lumbar puncture.—The needle ordinarily used for making lumbar punctures has at least two disadvantages. Its point has cutting edges, since it is formed by grinding down a fine tube until a point is made, and it has but one, a terminal, opening. Because of its cutting edges it is difficult to do a lumbar puncture with an

ordinary needle without wounding a blood-vessel; consequently the cerebro-spinal fluid obtained by its use is liable to be mixed with blood. When a lumbar puncture is done with an ordinary needle, the needle sometimes becomes blocked by a plug of skin or of tissue, punched out by its terminal opening. Even if the point of an ordinary needle is within the spinal canal the cerebro-spinal fluid may not flow freely, or may fail to flow, because the opening of the needle has been closed by a membrane lying over it. The needle has been designed in order that these disadvantages may be avoided. Its point is short and conical; consequently it has no cutting edges. Instead of one

terminal aperture this needle has three lateral ones. In order that all three of these openings may be in the spinal canal at the same time the distance from the upper border of the uppermost of them to the point of the needle is only a quarter of an inch and the openings face in different directions in order that all three may not be blocked by the same cause.

Fig. 3. Staining dish.—In order that a precipitate may not be formed upon films which are to be stained by a

¹ Memoir XVIII. of the Liverpool School of Tropical Medicine, p. 2.

watery modification of Romanowski's staining method ² they must be placed face downwards in the staining fluid. This is usually accomplished by resting the slides to be stained upon matches, or en other slides, and pouring the stain beneath them; the staining dish illustrated was devised to obviate this. It is made of glazed ware, and is capable of taking seven ordinary slides at a time. Along the whole length of the dish on either side run slightly raised margins, upon which the ends of the slides are supported. A shallow space is thus left between their under surface and the bottom of the dish, so that only a small quantity of stain is used.

JOHN L. TODE, M.D., Associate Professor of Parasitology, McGill University, Montreal.

CYANOPATHIA CUTANEA.

EXTRAORDINARY CASE OF THE MORBID TRANSPIRATION OF BLUE COLOURING MATTER THROUGH THE SKIN.

By Dr. C. BILLARD, of Angers.

(The Editor, after an introductory paragraph omitted now for want of space, concludes "Even though it may not be permitted to us to penetrate the intimate nature of everything presented by the study of natural philosophy, we should at least keep accurate records of all the curious and movel phenomena which may one day serve for the perfection of science. Under these impressions I proceed to publish briefly the subjoined case:—)

Victoria Russard, a full-grown girl, ætat 16, native of Corzi, department of the Maine and Loire, was presented to me [Dr. Biliard] for my opinion on the 23rd April, 1831, by M. Hervé, of Villeveque. Her face, neck, and upper part of the chest, was of a beautiful blue colour, especially remarkable on the forehead, the alæ nasi, and about the mouth. When her person was wiped with a white handkerchief, it was stained by the blue matter, and the skin was left clean and white; the lips were of vermilion tint, the pulse regular and natural, the strength and appetite indicative of perfect health. The only morbid symptoms she exhibited was a dry cough, but there was no rate, no dulness on percussion, no aberration from the natural phenomenon of the heart, at least as far as auscultation and percussion could demonstrate. years had elapsed since her first menstruation, which since continued to observe the regular periods. She followed the employment of a laundress, and from the commencement of this pursuit she began to perceive her eyelids dark and blue, and that this colour disappeared when she went into the open air. Any unusual increase of temperature remarkably augmented the blue secretion.

The coloration, however, made no progress till the end of last May, when the entire forehead and face became remarkably blue; the dry cough increased, and some sanguinelent expectoration, and at length hæmatemesis supervened. The menstrual function still was regularly performed. The patient was bled, and a blister applied to the arm without relief.

When I first saw this young woman, I imagined that the blueness was independent of any organic disease of the heart; and as the blue matter was secreted on the surface of the skin, which on its removal remained free from any stain, I deemed the secretion to depend entirely on an altered cutaneous transpiration. This diagnosis once established, I still found myself much embarrassed in the indications of treatment, and I at length ventured to advise the madicines, which, by their direct action on the skin, might induce some favourable modification in the disordered functions of that organ. With this view I prescribed six grains of flour of sulphur daily, and half an ounce of sarsaparilla moot in decoction in a pint of water.

Far from any success being thus occasioned in twelve days, abundant sweating ensued. The blue colour greatly increased. The forehead, the face, the neck, the chest, and the belly, became of a deep azure hue, which extended itself in clouds, grew pale or deep, according to the degree of acceleration or retardation in the cutaneous circulation; for example, when she was questioned on any delicate matter, instead of blushing she became quite blue. In fact the shades of the chameleon were not more sudden in their appearance. It is remarkable that the anterwar surface alone of the face, trunk, the shoulders, arms, and thighs, were susceptible of the tingeing, while the posterior surfaces remained free. The patient's linen was stained blue. The sclerotic coat, the nails, scalp, and concha of the ear, preserved their ordinary colour; the mucous membrane of the cheeks was rather pale, the tongue usually furred. There was no perceptible febrile movement.

Fifteen days after the first consultation, I again saw the patient. The blue colour was again increased; the cough stronger; no feverishness, but the urine had been so suppressed for six days, that for three days she had scarcely passed a single drop. Notwithstanding this suppression, she endured none of the accidents it ordinarily occasions, such as swelling of the abdomen, hypogastric pain, cedema of the ancies, &c. Every night there was profuse diaphoresis; some bloody sputa had recently been expectorated, for which she was bled in the arm. The blood exhibited no appreciable alteration from the healthy state.

I separated a considerable quantity of the blue matter from the skin by means of oil, it having resisted the action of water and vinegar. M. Cadot, an able and distinguished pharmaceutist, subjected it to the following chemical examination.

(We have not the space to transcribe the results of analysis of the blue matter, but no satisfactory conclusions were arrived at, except that Dr. Billard was led to administer bicarbonate of soda dissolved in an infusion of orange flowers, and in doses of from 6 to 18 grains daily, the use of which resulted in a diminution of the morbid secretion, and in 12 days the trunk was completely blanched, but there remained a slightly blue tint around the eyes, the alæ nasi, and the forehead. As olive oil had been found to remove the blue colour the patient was advised to wash her face with it every morning. Dr. Billard states: "This species of cyanosis is, I believe, unexampled in the records of medicine, this colouring matter here being widely different from the blueness of aneurismatic patients, or the greenness which sometimes is seen on stained linen.")

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN .- A quarterly court of the directors of this society was held on Oct. 13th, Dr. G. F. Blandford, the President, being in the chair. 19 members of the court were present. Since the last court one of the vicepresidents of the society, Sir Thomas Smith, Bart., had died, and a vote of condolence was passed from the chair. Sir Thomas Smith was elected a member in 1870, and had held the offices of director and vice-president. He had always taken the keenest interest in the welfare of the society, and was a regular attendant at the quarterly courts. of the annuitants of the charity, a widow, had also died since the last court; she came on the funds in 1907, and received in grants £145. The sum of £518 was voted to be distributed among the annuitants as a gift at Christmas, each widow to receive £10, each orphan £3, and the orphans in receipt of grants from the Copeland Fund £5 each. Membership is open to any registered practitioner who at the time of his election is resident within a 20-mile radius of Charing Cross. The subscription is 2 guineas per annum, or a member may become a life member by paying one sum the amount of which is fixed by the by-laws of the society. Relief is only granted to the widows or orphans of deceased members, and since the last court six letters had been received from widows of medical men asking for relief, but this had to be refused as their husbands had not been members of the society.

Application forms for membership and full particulars may be obtained from the secretary at 11, Chandos-street, Cavendish-square, London, W. The next election will be on The invested funds of the society now Jan. 12th, 1910. amount to £100,500.

LONDON: SATURDAY, OCTOBER 23, 1909.

Pathogenic Organisms and Sporadic Cases.

WHERE two cases of an infectious disease occur in patients in close proximity to one another the mode of transference of the morbid cause presents no need of any special explanation. The air may have been the medium of infection, and experiments have shown that The mode of transference may have this takes place. been mediate, clothes and other substances acting as the channel of convection, or immediate contact may serve to account for the transference of the disease. But the problem is far more abstruse when no other case of the disease has occurred in the immediate neighbourhood of the patient; and some supporters of the germ theory were in the early days of modern pathology compelled in defence of their opinions to invoke explanations which to our fuller knowledge appear improbable or even absurd. The power possessed by the air of conveying the microbes of disease is certainly of effect to some extent, but it is only in the neighbourhood of the patient that this mode of infection can act, and all recent investigations have merely served to increase the certainty with which this opinion is held, so that we hesitate to accept as conclusive any evidence which appears to point to pathogenic organisms being carried far by aerial agency.

Every year, however, serves to impress upon us more and more the importance of the ingesta as the channel of the infection of a very large number of microbic diseases, and the probability that even here the mode of entrance of the pathogenic organism may be unexpected. rôle of water as a medium of infection seems now to be fully appreciated, and many of the epidemics of typhoid fever and cholera are easily explicable by the hypothesis that the water imbibed contained the microbe of the disease. With other substances taken by the mouth the proof is often far from easy. In some cases the article of food has merely served to convey to the patient a small quantity of infected water. Thus the cases in which typhoid fever has been incurred from eating oysters might be regarded as due to the small quantity of water enclosed in the shell of the oyster, though the organism has been found within its body. And those other instances in which milk has been the medium of infection with typhoid fever may sometimes at least be ascribed to the washing out of the cans by infected water, some of the infected water being allowed to remain within the can. But occasionally the train of events is not so easy of explanation. For example, a question has arisen which has up to the present not received any satisfactory answer. If a cow drinks water or l

drinks from a pond containing bacillus typhosus, is it possible that the milk taken from that cow should contain the organism in a condition capable of causing the disease in those who drink the milk? The evidence on the subject is very scanty, but it would be unwise to deny the possibility of the occurrence of this mode of infection. In THE LANCET of Oct. 2nd of this year we gave a résumé of a case published in the Boston Medical and Surgical Journal of July 28th, in which typhoid bacilli were proved to be present in the milk of a suckling woman who was suffering from typhoid fever. As we remarked then, there is nothing very surprising in this fact. For many years it has been known that a large number of typhoid bacilli are excreted by the kidneys, in fact, it is customary to look upon the urine as one of the chief and most important media of infection, for there is always more likelihood of absence of care in disinfection of the urine than of the stools. This being the case it might be expected that the milk of a typhoid patient would be found to contain the bacillus. It is, of course, a different matter to assume that because the milk of a patient suffering from typhoid fever may contain typhoid bacilli an animal like the cow, in which the typhoid bacillus is non-pathogenic, could excrete with its milk typhoid bacilli which it has taken in by its alimentary canal; but that the sequence of events is imaginary it would be hazardous to say. In this and similar ways some of the sporadic cases which have proved so puzzling to epidemiologists may be accounted for, but the proof of the existence of typhoid "carriers" makes it hardly necessary for us to fall back upon such explanations. If a patient who has once had typhoid fever is capable after recovery from the disease of excreting daily large numbers of typhoid bacilli for many years afterwards, the occurrence of sporadic cases of the disease in neighbourhoods where no known case of the disease has existed is easily understood, and the evidence which was considered almost conclusive at one time of the origin de novo of this disease is now seen to be untrustworthy, because it is practically impossible to prove that some carrier of the disease had not passed through that neighbourhood within some weeks of the occurrence of the sporadic case. the same way, it is hardly to be doubted that most of the apparently inexplicable cases of isolated occurrence of infectious diseases would receive a satisfactory solution could we obtain fuller particulars of the life-history of those in the neighbourhood of the patient. An official report has just been issued by the Lieutenant-Governor of Bengal on an outbreak of cholera which occurred in the Presidency General Hospital, Calcutta, and from investigations carried out by Professor HAFFKINE it would appear that the epidemic has been traced by him to a custard pudding infected by the hands of some native servants who were employed for cleansing dishes and plates in the nurses' kitchen. Examination of two of these natives showed their hands to be infective with comma bacilli, and one of them on closer examination was found to be excreting comma bacilli in his stools while apparently in normal health. This is not the first instance in which a cholera epidemic has been traced or attributed to cholera "carriers." Last year an outbreak occurred at Manila in the Bilibid prison, and the medical authorities, suspecting that prisoners (who were infected without being actually ill) were disseminating the disease, caused the stools of 217 convicts to be examined. It was found that 17 of these were "carriers." A similar examination of 376 residents of Meisic, one of the worst cholera-infected parts of Manila, also showed that cholera vibrios were present in the stools of 27 of those examined. The alleged discovery of such "carriers" is of great importance, and if confirmed it will possibly throw light on many of the obscure epidemics and sporadic cases of cholera that occur from time to time.

But because the existence of "carriers" may account for so much we must not try to make it a universal solution of difficulties. The more widely our knowledge of the bacteriology of food extends, the more is it borne in upon us that many articles of diet are liable to become the channels of infection. Recently it has been shown that the eggs laid by a tuberculous hen may contain living tubercle bacilli, and if this be true of tuberculosis it is far from improbable that many other pathogenic organisms may be able to gain an entrance into the body through the same vehicle. It may be urged that as eggs are almost always cooked before being eaten the risk of infection from this source is but small, but the cooking which an egg usually receives is quite insufficient to destroy the vitality of included micro-organisms. When an egg is lightly boiled the proteids of the yelk are not coagulated. Therefore, it is practically certain that any organisms contained therein could not be destroyed by the temperature to which the egg is subjected. Too much stress is often laid on cooking as a sterilising process. It is true that there is no other method to be compared with heat for efficacy in destroying the micro-organisms of disease, but it is rare indeed that cooking is effected at such a temperature as to sterilise the food. The interior of a loaf, even while it is in the baker's oven, never reaches a temperature sufficient to destroy living microbes, though the outside may be baked brown. This has been conclusively shown by enclosing within the interior of a loaf sealed glass tubes containing living germs. And what is true of bread is true also of meat, which is not subjected in the most thoroughly roasted joints to a temperature sufficient to be efficacious against diseases. Even when a joint is boiled and the water in which it is placed is kept at a temperature close to the boiling point, the interior has a much lower temperature. The mere fact that the interior of a joint is usually red is a conclusive proof that it has not reached the temperature of boiling water. Some processes of cooking are more efficacious than others, but the chances of the introduction of pathogenic germs in food are very great indeed, so great that the occurrence of sporadic cases of epidemic disease needs no further explanation.

One fact alone stands between us and widespread attacks of these infective diseases, and that is the naturally defensive powers of the body. Day by day all of us must take in by the air we breathe numberless pathogenic organisms; day by day we imbibe with the water we drink and with the food we take innumerable germs which, should the conditions be favourable, can give rise to disease. But fortunately

for us the conditions are generally not favourable. The natural resisting powers of the body are sufficient to counteract all these assaults of our invisible enemies, and we survive, not because we are not attacked, but because our tissues are able to withstand the attacks made upon us. In what manner this defensive power of the body may be lowered we know at present little, but advances in prophylaxis will be made by the prevention of these reductions in our defensive powers. This is the promise of the latest developments of pathology.

National Temperaments and the Ferrer Riots.

THE tragedy of Montjuich has provided the world with an object-lesson in the contrasted behaviour of the Latin and non-Latin races after the fall of the curtain on the last tragic scene. While in the English-speaking communities as well as in the German, Scandinavian, and Slav the incident has called forth profound pity for the protagonist and modified censure (pending fuller information) on the methods by which he was brought to judgment, in their Latin sisters it has evoked the most passionate, even hysterical demonstrations, proceeding to violence, against every person or thing associated, however remotely, with his supposed executioners, and exploding in collisions with the police and the military, causing civic uproar and death itself. The improvised indignation meetings, followed by processions of infuriated mobs bent on damage and destruction to the Spanish Embassies and Consulates in the chief French and Italian cities, have disturbed the peace of Europe with a repetition of deeds of violence wanting but little to reproduce some of the worst episodes of the Reign of Terror. Barricades have been run up and frantically defended, all business has been interrupted, and when, after much drastic, even sanguinary, effort, tranquillity has been restored, a general strike has been proclaimed which has, in Italy, paralysed for the time all industrial or commercial operations, and intimidated alike the citizen within and the stranger without the gates.

Whence this contrast between the demeanour of London and Berlin on the one hand, and that of Paris and Rome on the other? The better minds of the two latter cities, as conveyed in its more serious press, find the answer in racial idiosyncrasy—the Teutonic circumspection and self-control sufficing to maintain calm in presence of a provocative to which the Latin super-sensitiveness and blan blindly abandons itself. The comments of such journals as the Temps or the Corriere della Sera give emphatic expression to this finding, while other organs, French and Italian, repeat it with the invoked authority of HIPPOLYTE TAINE and KARL HILLEBRAND, both of whom in their comparative studies of their respective nationalities insist on the differentiating qualities to which Tennyson makes poetic allusion in the lines—

"Bright and fierce and fickle is the South, But dark and true and tender is the North."

TAINE, indeed, in his penetrating analysis of the Latin mind, goes so far as to say that France, and a fortiori Italy, owe much of their hyperæsthesia to not having been adequately

"Teutonised"—in other words, to not having had that proportion of the "northern infusion" which would have corrected, while not wholly crushing, inherited character, and culminating in a racial blend which, in Great Britain, for example, is manifested in the happy equipoise of Celt and Saxon, Norman and Dane. Time, plus education, may be expected to achieve a similar result in the Latin civilisation, aided as these will be by the intercourse now in rapid progress between race and race—intercourse facilitated, inter alia, by international congresses in every interest, scientific, literary, artistic, and professional.

Meanwhile it is impossible not to be impressed with the bitter irony with which the most widely diffused of Italian journals-the Corriere della Sera of Milan-contrasts the demeanour of its compatriots with that of the Englishman and the German in view of the so-called "martyrdom" of FERRER. In Germany and in England, it points out, the incident has produced no riots, no window smashing, no barricades, no dragonnades, no bloodshed, and yet in these countries there has been no lack of sympathy with FERRER or sober questioning of the procedure by which he was made to atone for his propaganda. In Germany, it continues, there is a powerful Socialist party, while England is so much the "land of liberty" as to have become the "second country" of the anarchist refugee; and yet how different their public behaviour after the events of Montjuich. But in Italy, says the cruel Italian newspaper, "we are so much more ardent, so much more impulsive, so much more susceptible! When our delicate appreciation of liberty and of justice is outraged we explode, we 'strike,' not work only, but everything and person that offends us. We are built so!" Mordant words these, coming from an able and cultured organ of public opinion; but not, we fear, given forth for the last time! "Fanciulli siamo" (children we are), said MASSIMO D'AZEGLIO, after the declaration of his country's unity and independence. "We have made Italy. We have now to make Italians." Uttered well-nigh 50 years ago, these words are scarcely less relevant in the day now passing; nay, they will continue to have their relevance till Italy realises the superiority of deeds to words in the development of a true sense of citizenship shown in a purer, higher standard of official responsibility, till she abandons short cuts to the millennium in favour of that more excellent way of steady, intelligent, undeviating work on the lines of duty, of self-abnegation, and of enlightened brotherhood.

Some Considerations of Medical Education.

THERE can be no doubt whatever that medical education supplies to thoughtful members of our profession more problems for close contemplation than almost any topic of the present day, and when we consider all that is meant by following the calling of medicine at the beginning of the twentieth century it is not surprising that there should be difficulty in training the recruits for that calling, or that there should be differences of opinion concerning numerous matters of equipment. To begin with, more than in any other unit of society the medical man has within his calling

a choice of varying careers, the careers in some instances being so totally different that it seems well-nigh impossible that any general course of training should be equally adapted for all of them. Of course, all medical men have common scientific and humane objects—namely, to eliminate disease either by prevention or by treatment; and all medical men are alike in desiring that their services should be reasonably rewarded by the public. Incidentally, we may state here that if expectations with regard to the elimination of disease are sometimes not realised, expectations with regard to earning an adequate wage are with equal frequency doomed to disappointment; but these unfortunate facts do not alter the common aims and hopes of the medical man, in the carrying out of which the methods of life adopted are extremely diverse.

First there is the practitioner, who is divided into the general practitioner, the consultant physician, and the consultant surgeon. Their lives have much in common and the education which they require is, up to a certain point, identical in all three classes. But the life of the general practitioner is a much less sheltered one and demands a knowledge of men and manners and a familiarity with business of which the consultant practitioner, great psychologist, versatile operator, and astute humanitarian though he well may be, need have no conception. Next we have the official medical man, the medical man whose whole time is occupied by sanitary, educational, or official appointments. The lives of these men are approximated closely with the lives of the upper-class bureaucracy, with the exception that in most of the public departments of the State the officials are better paid and are only expected to work between certain hours, while medical officers of health are always on duty. True, when times of stress occur in any of our public departments -the Education Office and the Admiralty are two that occur to the mind at once—no regard whatever is paid to official time, but everybody has to work as long and as hard as human endurance will allow; but this occurs on special occasions, and to a certain extent there is proper warning of its occurrence given to the chiefs. Our sanitary authorities are not so fortunate, and their medical officers, though affiliated on the one hand with the bureaucracy, share, on the other, with their brethren, the general practitioners, the greatest hardship of the medical profession-viz., that no medical man knows from day to day or from hour to hour when he may be called upon for special exertions. Yet another class of the medical profession lead the lives of pure savants—for them the laboratory is the world. They join hands with members of the medical profession at every therapeutic discussion, reinforcing the clinical tactics of the general practitioner with the etiology and the therapeutics which have been worked out with the microscope, at the chemical bench, or in various departments of physiology, psychology, biometry, and so forth. Lastly, the three Services -namely, the Naval Medical Service, the Army Medical Service, and the Indian Medical Service—and a fourth, the Colonial Medical Service, must be mentioned. They provide caroers again differing in detail among themselves and differing in many respects widely from any followed by other branches of the medical calling. This rough analysis of the classes into which the medical profession in this country falls shows at once that it would be extraordinary if differences of opinion did not arise with regard to any educational curriculum more or less designed to be suitable to the needs of all medical students.

At the beginning there is the difficulty of deciding the point up to which education must be common to all classes and where some account should be taken of the intention of the student to devote himself to one or other particular class. Everybody allows that in a liberal profession like medicine it is necessary that all the members should have a general education up to a certain standard, but as to what that standard should be there is no agreement. We have heard extremists say that every medical man should go to a university and take his degree in arts before commencing his medical career. There are, of course, men whose cast of mind is such that the proceeding exactly suits them, but there are others for whom such a measure of general education would never have any meaning at all, it would not help them in the least to develop in a useful manner, and further, it would be quite likely to nip in the bud powers of initiative and originality of impulse that would otherwise come to the front. The ideal general education, sufficiently high in standard to give its possessor the power of grasping professional subjects, and yet not so high that unnecessary time and labour have to be spent in the acquisition of the completely useless, will always be a subject of debate. All that need be said on the matter in these introductory remarks is that the examination which suits the bent of the largest number of students is probably the right one, while no standard can suit everyone. Then we come to medical education proper; and here again we find the same differences of opinion as to necessary standard. Medical education is divided into preliminary or ancillary subjects and purely professional subjects, but not divided with any sharp line. All instruction in the practice of medicine is of course a purely professional matter, while instruction in the sciences upon which medicine is directly founded-viz., anatomy, physiology, psychology, chemistry, and physics generally—is more or less preliminary. Anatomy and physiology may be termed more directly professional subjects than the others, but chemistry, for example, having regard to modern developments of bio-chemistry, can hardly be regarded as a merely ancillary subject.

With these things in our mind we are prepared to find that the subject of medical education bristles with numerous and difficult points for debate. In addition to the necessity that the general education of the medical student should be conducted to a point which is not agreed upon, and in addition to the fact that the subjects which are really germane to medical education are not settled beyond dispute, we may have to consider what amount of specialisation is necessary in a curriculum which must be designed to fit young men for the very varying careers which, as has been indicated, will lie before them. Here, again, the extremist, having first said that everybody should have a university degree in arts before he begins to do his professional work, may be found saying that everybody should have a university degree in medicine before he attempts to specialise, and that such subjects as public health and hygiene, the use of medical statistics, and the

technique of pathological developments should all be acquired as post-graduate subjects, the curriculum being merely designed to bring everyone up to a standard from which he can safely diverge along a special path. These are some of the questions the discussion of which is begun to-day in a short series of articles in our columns.

Annotations.

"Ne quid nimis."

EXPERIMENTAL PSYCHOLOGY AND HYPNOTISM.

THE Harveian Oration for this year was delivered before the Royal College of Physicians of London on Monday last, Oct. 18th, by Dr. G. H. Savage, consulting physician and lecturer on mental diseases at Guy's Hospital. The lecturer. after a sympathetic sketch of the life of Harvey and the times of unrest, social, moral, and political, in which he lived, went on to consider briefly the treatment of the insane during Harvey's day. He quoted from Shakespeare and Robert Burton, the author of "The Anatomy of Melancholy," and adduced other examples from Hack Tuke's well-known "History of the Insane in England" to show how the treatment of insanity in this country has steadily progressed from gross superstition and from a cruel punishment of the deranged to the present position of enlightened care, with its promise of further development along the lines indicated by the work of Dr. F. W. Mott and Dr. Henry Head. Having in this way reached what he called the nucleus of his address. Dr. Savage spoke in weighty terms concerning experimental psychology and hypnotism. The object of experimental psychology he said to be "to describe the complex in the terms of the simple."

From one aspect, a certain mixture of hydrogen and oxygen is identical with an equal mass of water. Although the hydrogen and oxygen remain undestroyed during the transformation into water, we cannot overlook the fact that important alterations have taken place in their relationship to one another; they are fused, and are no longer a mere mixture. So, too, in psychological examples several tonal sensations fuse to create a new expression of temper. But both chemistry and psychology must recognise the inexplicable nature of the fusion. But this is more suggestive than exact, as the personality of the subject has to be added and considered. In the study of sensation experimental psychology proceeds hand-in-hand with the physiological; but, in regard to memory, comparison and mental work, we are indistinctly connected with a physiological basis. It is only in comparatively simple conditions that the physiological worker can accurately predict what reaction will recur with a given stimulus. The living body is characterised by unknown vital activities, as well as by known mechanical activities. The variability, not only among individuals but in the same individual, is supposed to be against the existence of any science of experimental psychology; but the object is to study Nature, and the variations and properties of mind are affected by different conditions. It is the aim of all science, and the sim of experimental psychology, to analyse, as far as possible, the conditions which may be at work, and to determine the result which must follow provided that these conditions exist.

With regard to hypnotism Dr. Savage's welcome of modern work and recent developments was no less frank. He said that he felt strongly that the time had come when the medical profession must face the fact that though in all directions there is a tendency towards credulity it was absolutely necessary that science should explore and develop the hinterland of philosophy and psychology, and especially the relationship between hypnotism and medical and surgical treatment.

"It has now been found," he said, "by long experience, that there are certain forms of disorder that are better treated by hypnotism than by anything else. It is quite certain that hypnotism alone may not be all that is required, and there. I think, a mistake is frequently made. It is thought that it must be hypnotism and nothing else. But one's experience is that surroundings and general conditions are as important for the treatment as the hypnotism itself...... Many nervous cases might be cured without hypnotism, but such cases, in many instances, would be cured more quickly and more satisfactorily by the use of hypnotism. It is certainly contra-indicated in the very highly neurotic. I think those coming of very insane stock should rarely be subjected to its influence. Those who are actually insane are rarely, if ever, influenced by it. Epileptics, as

a rule, do not benefit in one way or another. To put it shortly, nervous disorders that do not depend upon organic brain disease, those mental disorders that are purely functional, and such as do not cross the insane border-line, may be benefited. It has been said against hypnotism that it treats symptoms and does not treat the disease, but it seems to me pretty certain that in many cases if you can alleviate the symptoms you go a long way to cure the disease. In fact, in many cases the symptom is the most serious question; if, for instance, pain is disturbing digestion, rest, and general mental capacity, the relief of pain places the patient on an altogether different footing to that on which he was before. In the same way with sleeplessness. It you can relieve sleeplessness, in many cases the fundamental cause of that sleeplessness may be better treated."

The importance of experimental psychology is becoming generally recognised by the medical profession, and though until recently this country has decidedly lagged behind in the matter of practical investigation, there is now a mass of work being done of great promise for the future.

THE REMOVAL OF SNOW IN THE STREETS.

This is not a violent forecast of winter in mid-autumn. but it is just as well to be reminded of the problem of the removal of snow in our streets before the season approaches when we may expect a visitation. There can be little doubt that a snowfall in a busy city is not only a source of inconvenience and of hardship to traffic, but of prejudice to the health also. According to a useful plebisoite of opinion recently obtained by the town clerk of Lambeth on the question, it would appear that in 10 cases of British cities-namely, Aberdeen, Bradford, Bristol, Greenock, Inverness, Leeds, Leicester, Newcastle, Nottingham, and Paisley—the opinion is that a general use of salt for the removal of snow is objectionable from a public health point of view. In the majority of these opinions it is stated that either slush of a low temperature or a freezing mixture is formed which is at least unpleasant for, if not dangerous to, pedestrians, and is distinctly injurious to animals' feet and to foot passengers with defective footwear. The medical officer of Nottingham states in addition that the use of salt is objectionable on account of the deliquescent salts of magnesium present. From other cities various views come. There is a difference of opinion at Edinburgh and Hull, at both of which places salt is used. In both cases the medical officer is strongly of opinion that the use of salt is an objectionable practice, on account of the low temperature of the mixture and the danger to horses' feet and the footwear and health of pedestrians. The city engineers, on the other hand, are in favour of the application of salt. In the case of Hull the city engineer states that he has made copious inquiries amongst horse owners, the majority of whom were urgent for its use, and in addition the temperature of salted and unsalted snow has been taken without any measurable difference having been found. This is a curious finding, because the snow in melting necessarily depresses the temperature, the use of freezing mixtures being based on that fact. The city engineer's opinion is that without applying salt it is impossible to maintain traffic on wood paving. The city road surveyor of Edinburgh considers that salt does no appreciable injury to paved roads, but tends to break the surface of macadamised roads. The medical officers of Dundee, Liverpool, and Manchester consider that no actual harm results from the method of applying salt in their respective cities, though in the case of Manchester it is stated that no doubt people with defective boots suffer severely. At Glasgow the need for salt is so infrequent that the medical officer considers it would be difficult to separate out the illness attributable to the use of salt from the general mass of lung troubles prevalent in snowy weather. The opinion of the medical officer of Leith is that the question is not one influencing public health, save from the danger to persons by saturated footwear. The medical officers of Birmingham, Norwich, and Sheffield do not express any

opinion on the matter. In the cases of Berne, Copenhagen, Frankfort, and Leipzig it is stated that no decision has been arrived at as to the advantages or disadvantages accruing from the application of salt, whilst from Breslau and Munich no reply has been received to the question. In the opinion of the authorities responsible for the clearing of the snow at Antwerp, Berlin, Dresden, and Hamburg, the use of salt is prejudicial to public health, the usual grounds for objection being alleged; the reply from Antwerp also states that if small quantities of salt are mixed with ashes the practice is not objectionable when applied to roads first cleared of the bulk of the snow. Some years ago at Amsterdam certain of the tram horses' feet were said to have become diseased through the use of salt, but no complaints of injury to persons have been received from this city; the opinion is expressed, however, that people whose footwear is impregnated with the mixture of salt and snow are apt to catch cold. It is reported from Paris and from Christiania (in which latter place, however, salt is not used except at points and switches only of the tramways) that no danger or disadvantages arise from the use of salt. The opinion at Cologne is that the interest of public heath is little influenced by the use of salt. Salt is used very sparingly and snow is removed immediately at The Hague, so that no complaints as to its use have as yet been made. However effectual salt may be in removing snow, there can be little doubt that the resulting mixture is most unpleasant to pedestrians, and inasmuch as even good leather does not appear to be proof against the cold slush, there is reason for believing that the mixture gives rise to injury to health. It is a pity that flooding snowbound streets with a plentiful supply of hot water is so far impracticable in our cities.

"LATE RICKETS."

WE publish on another page of our present issue an interesting note by Dr. Francis Hernaman-Johnson on a case of the type to which the term "late rickets" is often applied. The patient was a girl, aged 13 years, without any history of rickets during infancy, who at the beginning of her menstrual life began to have difficulty in walking and subsequently developed bending of the legs. This was followed by extensive deformities of the lower limbs and by a left dorsal scoliosis. In spite of treatment by instruments and by prolonged rest the condition, apart from a temporary amelioration while in bed, showed no improvement while under observation. The unfortunate application of the term "rickets" with or without a qualifying adjective to almost any condition producing general deformities in the bones in infancy and childhood has undoubtedly led to confusion and has probably hindered the recognition and separation of some obscure conditions of disease or defect in ossification. That various causes may produce gross results apparently similar is highly probable in regard to a process such as ossification in the skeleton, where many of the resulting deformities depend upon the effects of posture and upon the support of the body by weakened limbs. What is wanted in these cases is further information as to the histological and chemical changes associated with them. Dr. Hernaman-Johnson very rightly points out that in his case the relationship with infantile rickets appears more than doubtful, and asks if it is not wiser to admit frankly that we do not know the etiology of such conditions. There can be little doubt that the term "late rickets" is applied to several distinct affections. It is possible, as Dr. J. F. Goodhart and Dr. G. F. Still suggest in their well-known work on "The Diseases of Children," that some of the cases may be due to recrudescent rickets, since there is no obvious reason why similar changes may not develop during later childhood

to those that occur in the infantile period, seeing that the skeleton is still in an active state of growth, and in a case recorded by Dr. F. G. Dawtrey Drewitt the changes found post mortem in a boy aged 11 years presented characters similar to those in infantile rickets. Probably some of the cases are due to a process akin to osteomalacia or to some as yet unrecognised disturbance of the process of ossification. Owing to the comparative rarity of these conditions observations on fatal cases are extremely few, and it is to be hoped that all such cases will be recorded. It is of interest to note that Dr. Emmett Holt 1 states that he has not seen this disease and that no case has been seen during the past 20 years at a hospital in New York where large numbers of deformities are seen. Dr. Hernaman-Johnson suggests as a possible factor in the etiology of some of these cases some change in the internal secretion of the generative glands, since some of them occur, as in the case which he narrates, at puberty, and he points to the bony and arthritic lesions which may occur during pregnancy and at the menopause in support of this suggestion.

PATHOLOGY AND THE STAGE.

THE translation of a play by M. Brieux is now being acted at His Majesty's Theatre. M. Brieux is one of the chiefs of that interesting group of French dramatists whose subjects have been drawn from the realm of pathology or from that of legal medicine. His writings, along with those of François de Curel, Bruyerre, Henriot, Le Senne, and Mayer, have been discussed and described at some length by M. Eugène Eyriès in a Montpellier thesis ("Les Idées Médicales dans le Théâtre Contemporain"). According to this writer, M. Brieux has not hitherto been favourably known from the scientific point of view. His earliest work. "L'Evasion" (1896), deals mockingly with ideas about heredity and is a violent attack on medicine and its practi tioners. "Les Remplaçantes" deals with wet-nursing and the highly contentious question of the endowment of motherhood, and "Les Avariés," censored in Paris in November, 1901, has for its subject the marriage of persons with constitutional disease. These are pathological plays on subjects which cannot properly be treated outside the sphere of professional or expert literature. A folk-lore play, however, is on quite a different footing. And "False Gods," the translation of M. Brieux's "La Foi," is emphatically a folk-lore play. No one can object to a satire on medicine in a drama purporting to present an accurate picture of pre-historic times. In "False Gods" the medical man of ancient Egypt is represented as a sorcerer in league with the funeral dancers, who themselves represent the undertaker of modern times. In his character as magician he utters highly poetical incantations over a dying man, who is relieved when he (the sorcerer) gives up the case with the remark that the evil spirits are winning in the fight over the perishing body and that he will send the funeral dancers round. Akin to the sorcerer medicineman is the High Priest, impersonated with infinitely dry humour by Sir Herbert Tree. This personage sums up the philosophy of the ancient Egyptian priesthood in the short lecture delivered by him to a recalcitrant young priest. "Of course," says the High Priest in effect, "we Egyptian priests don't believe a jot of what we profess, but we are wise enough to keep the people in the trammels of superstition in order that they may support the hierarchy with their offerings of corn. Nor are we to blame in fleecing them in times of prosperity, for thus we fill the granaries against periods of famine. In the same way we bid the people worship the jackal and the bull, for the jackal is a useful

scavenger and the bull is responsible for the continuance of our meat-supply." Such, in effect, was the doctrine of all primitive priestly castes, of the Egyptian, perhaps, especially. Apart from its art, such a play as that now being acted at His Majesty's Theatre is interesting as showing that medical ethics really have improved in the course of ages, and that the deception of the public for their good has long ceased to form part of an esoteric philosophy of the scientific or of the governing classes. The modern scientific spirit aims at getting the support of the public by enlightening them, not by frightening them.

THE CRITERION OF COLOUR.

THE impressions which the public have in regard to the colour of food are interesting, but their instinct in this matter may easily be deceived by modern tricks. For some not quite clear reason there are many people who look upon the brown egg as necessarily a new-laid one, and hence a fair demand for brown eggs has arisen, which is easily met not by the honest brown egg, but by the white egg which has been steeped in a dye which renders it visually indistinguishable from the real article. Again, when milk happens to be of a buff tinge it is commonly held to be richer than white milk. Of course, nothing can be easier than to satisfy this preference for a milk of a creamy shade. White-looking butter is disliked as looking too much like dripping. The remedy is simple: it is artificially coloured. Vegetables must be bright green to make them look fresh, the consumers of them being quite willing to ignore the fact that copper does not make them fresh or wholesome. On the other hand, curiously enough, bread must be white, and not the slight brownish colour natural to the flour from which it is made. It is, of course, perfectly natural to take colour as a criterion of the dietetic value or flavour of food, and the attractive or unattractive appearance of food may make all the difference as to whether that food is, or is not, assimilated properly. The deceit which is practised by artificially colouring food may thus serve a useful purpose, so long as the colouring matter is harmless, but as a rule the proceeding is an immoral one. It does not follow that because food is unattractive its value as a food is nil, while every form of sophistication is open to commercial abuse. A correspondent last week submitted to us a brown-shelled egg which on opening displayed a gorgeous red colouring scattered chiefly through the white. On analysis the colouring proved to be an aniline dye. The dye had deposited a nice brown on the shell, but an excess had permeated its pores and, meeting with the slightly acid contents, was changed to a port-wine Until the egg was opened, therefore, it colour inside. appeared perfectly attractive, but on opening it the zest to eat it quickly disappeared. There is practically no control over the colouring of foods in this country, and it is obvious that in some instances protection is desirable. If colour is used to give a false appearance of quality there can be no doubt about that being fraud, but whether it is a mischievous fraud depends on particular circumstances.

ASTHMA AND URTICARIA DUE TO AN ICE-CREAM.

In the Australasian Medical Gazette for August Mr. T. I. Wallace has reported the following interesting case. He was called to a woman who suddenly became ill in a shop where she had taken a glass of ice-cream followed by a tumblerful of cold water. In a few minutes she was seized with great dyspnœa, accompanied by running at the nose, lacrymation, and sneezing. Her mother, who was with her, said she became black in the face. Mr. Wallace saw her about a quarter of an hour after the beginning of the attack.

¹ Diseases of Infancy and Childhood, fifth edition, 1909.

She was sitting on the edge of a bed in a room behind the shop and was feeling a little better. She had still great difficulty in breathing and in consequence was unable to lie down. Her face was very cyanosed, there were free running at the nose and watering at the eyes, and she was covered all over with an abundant urticarial rash. There was a history of one or two similar attacks in childhood which were brought on by drinking cold water when she was over-heated. In a short time she improved and could be taken home. The association of the urticaria with asthmatic symptoms is of considerable interest. It bears out the hypothesis of the late Sir Andrew Clark, which is not generally accepted, that asthma is due to a vaso-motor neurosis analogous to that which occurs in the skin in urticaria. It is well known that in rare cases of urticaria, particularly in the form known as giant urticaria, or acute circumscribed or angio-neurotic cedema, mucous membranes, such as that of the tongue, stomach, intestines, or larynx, may be involved. Angio-neurotic ædema of the larynx may cause sudden death by suffocation. The association of asthma with urticaria is a recognised but rare event; in some cases an attack of urticaria has appeared to take the place of an attack of asthma.

THE TREATMENT OF VIPER BITES.

THE bite of the only venomous snake of this country is rarely recorded in the medical journals, partly because this form of injury only occasionally occurs, but also partly because vipers are most numerous in out of the way parts of Great Britain. The entire absence of the viper from Ireland and the Isle of Man is very remarkable, whether we accept or reject the legend which ascribes it to the action of St. Patrick. Even should a person be bitten by a viper a fatal result is rare, though severe symptoms are always produced. Occasionally, however, death follows the bite of a viper, and it is desirable that all medical men practising in the country should be acquainted with the best treatment of this injury, for the earlier in the case the remedies are applied the more effective they prove. On another page of our present issue we publish an account by Dr. B. B. Sapwell of Aylsham of a boy being bitten on both hands by a viper. Much shock followed, with enormous swelling of the hands and forearms. The treatment adopted consisted in the application of a Bier's elastic bandage to each arm above the elbow, incisions into the swollen part. and the local application of permanganate of potassium. Later some antivenom serum was injected, and ultimately recovery followed. Several points of interest are raised by the treatment adopted. The use of the Bier's bandage doubtless served to restrict the absorption of the poison without interfering with its arterial blood-supply, and the incisions not only relieved the tension of the parts but allowed the draining away of the venom-infected lymph. It is probable that the employment of Bier's suction method to the bites would have been efficacious in abstracting the poison, especially as the bites were inflicted on fingers to which Bier's glasses could easily be applied. The value of the permanganate of potassium in snake bites has often been shown, but it can hardly reach much of the venom, though where the poison can be reached the permanganate is able to destroy it. The main interest, however, attaches to the use of the antivenom serum. This, as sold in this country, is prepared by the use of the venom of several of the more poisonous snakes, including the cobra and the daboia, and it has been shown to be efficacious against a very large number of them. In the case to which we have referred it appears to have been of use, and it is clear that it did no harm. It should certainly be injected in all cases of viper bites, and the sooner this is done after the infliction of the injury the greater the probability of success. The main

obstacle to its use is the difficulty of obtaining it promptly elsewhere than in the chief towns. We referred to this subject in THE LANCET of August 21st last, p. 585, when we summarised Professor Calmette's directions for the treatment of viper bites. We congratulate Dr. Sapwell on the success which attended his prompt and intelligent course of treatment.

THE WORKING OF THE MIDWIVES ACT.

AT an inquest recently held in the City by Dr. F. J. Waldo several points came under discussion in connexion with the operation of the Midwives Act, 1902. A medical man had been called in to a confinement under the advice of a midwife, given under her statutory obligation to do so, and he had attended, as he stated was his practice, without any certainty or, it might be added, any expectation of receiving a fee for so doing. This hardship has now continued for some years, although locally some attempts have been made to abate it. It is a matter in which the proper remedy must come from the legislature which has created the difficulty, and the Report of the Departmental Committee on the Working of the Midwives Act has endorsed this view so strongly that we can hardly imagine that the abuse will go long unheeded. The question of who may be adjudged ultimately liable should not affect the safety of the patient or the position of the medical practitioner. The midwife acting under the rules of the Central Midwives Board has been compelled to advise that he should be summoned, declining, meanwhile, to attend alone; and owing to the form in which the summons is sent it is in effect the midwife's appeal for medical assistance, although, strictly speaking, it is that of the patient or her relatives acting on the midwife's recommendation. At the inquest before Dr. Waldo it was not shown that any blame attached to the midwife in respect of her attendance, the body being that of a child for whose still-birth natural causes had been responsible. The qualification of the midwife was, however, inquired into, and it was found that she had been struck off the midwives' roll two years before, and her request for re-instatement had not been granted by the Central Midwives Board. She was an Austrian, and the father of the child was a German Pole. It will be remembered that at present this woman, as any other, whether enrolled as a midwife or not, is permitted to practise as such, but not to take or use the title of midwife or any other description or title implying that she is certified under the Midwives Act, 1902. After April 1st, 1910, however, a new state of affairs will arise and uncertified women will be forbidden by law to practise at all. The subsection dealing with the matter may be quoted, as the time is drawing near for its legal enforcement and, as will be seen from the wording employed, such a process is not likely to be altogether easy.

Section I., Subsection 2: From and after April 1st, 1910, no woman shall habitually and for gain attend women in childbirth otherwise than under the direction of a qualified medical practitioner unless she be certified under this Act. Any woman so acting shall be liable on summary conviction to a fine not exceeding £10, provided this section shall not apply to legally qualified medical practitioners or to anyone rendering assistance in a case of emergency.

It will be seen from this that the offence to be proved against an uncertified woman acting as a midwife will not be that she so acted in a single case, for hire or otherwise, but that she does so "habitually and for gain." The two essentials of habitual practice and of remuneration will often not be found easy to establish, and presumably if proof of two or three cases only is adduced the defence that "assistance was rendered in a case of emergency" will frequently be raised. It will be interesting to see how this section works in practice. It will not be forgotten that it involves a principle of great importance, affording, as it does, to parturient women

a protection against women not qualified to attend them. Similar protection in pathological troubles is not vouchsafed to the other members of the public or to women not in child-birth. Other unqualified practice of medicine and surgery remains uncontrolled and women in childbirth can employ "men midwives" who are unregistered, so long as these men do not pretend to be on the Medical Register.

EXOPHTHALMOS IN CHRONIC NEPHRITIS.

In the American Journal of the Medical Sciences for October Professor L. F. Barker of the Johns Hopkins University and Dr. F. M. Hanes have called attention to a remarkable sign of chronic nephritis which does not appear to have been previously noticed—exophthalmos. During the first four months of the present year 33 patients suffering from chronic nephritis were admitted to the Johns Hopkins Hospital, and exophthalmos was found in 16 (48.4 per cent.). The exophthalmos varied much in degree as did the gravity of the nephritis. In cases showing evidence of serious intoxication (uramic or suburamic symptoms) exophthalmos was most frequent and was combined with one or more allied ocular signs-anisocoria, von Graefe's, Moebius's, or Stellwag's sign. Exophthalmos was an obvious sign in all the patients who died from chronic nephritis in the hospital since Jan. 1st, 1909. Also in the cases in which albuminuric retinitis was present during this period exophthalmos, with one or more of the other ocular signs, was always present. All these classical signs of Graves's disease may be present in chronic nephritis without any apparent affection of the thyroid gland. Professor Barker and Dr. Hanes therefore conclude that in both diseases a chronic intoxication affecting the sympathetic nervous system causes the ocular manifestations. In 12 out of the 16 cases there was high blood pressure (above 160 millimetres), but its absence in the other cases shows that the exophthalmos cannot be ascribed to it. Evidently both conditions are due to chronic intoxication. The following are two of the cases. A painter, aged 51 years, and addicted to alcohol, was admitted on Jan. 15th, 1909, complaining of severe pain all over the body and headache. In 1901 he was treated for lead poisoning and peripheral neuritis. He was subject to severe headaches as long as he could remember. His sight had been failing for the last five years and for the last two years he had suffered from attacks of palpitation and orthopnœa. He passed large quantities of urine by day and night. He was thin and ansemic, and his skin was dry and harsh. The eyes were prominent and staring. The heart was slightly enlarged and the arteries were sclerotic. Ophthalmoscopic examination showed albuminuric retinitis, cedema, exudation, and hemorrhages. The urine was pale, of specific gravity 1012, and contained albumin, many granular casts, and pus and epithelial cells. On the day after admission convulsions occurred, and on the following day the patient died. At the time of death the exophthalmos was much less marked. The necropsy showed advanced acute and chronic diffuse nephritis, cedema of the brain, hypertrophy of the heart, broncho-pneumonia, pleural cedema, and acute pericarditis. In another case a metal polisher, aged 46 years, was admitted on March 4th, 1909, complaining of shortness of breath and pain in the back and left side. His illness began four weeks before with dyspnœa and palpitation. He got up six or eight times at night to pass urine. His legs were sometimes swollen in the mornings. He was well nourished. The eyes were very prominent and the conjunctivæ were alightly edematous. The pupils were small and reacted to light. Moebius's and Stellwag's signs were present. There were marked retinal arterio-sclerosis and typical albuminuric retinitis. The heart was enlarged and marked general

arterio-sclerosis was present. The urine was increased in quantity, pale, of specific gravity 1012, and contained albumin and hyaline and finely granular casts. The blood pressure was high, ranging from 200 to 230 millimetres of mercury. The patient's family said that his eyes had grown prominent in the last eight months.

PROFESSOR OSLER'S ADVICE TO LONDON STUDENTS.

On Oct. 15th Professor William Osler visited the London Hospital to declare open the new laboratories for chemistry, physics, and pathology, which have been erected recently at a cost of some £8000. He was received by the Principal and the Vice-Chancellor of the University of London. Mr. Sydney Holland, chairman of the hospital, and the staff and lecturers of the hospital, who conducted him through the new laboratories, after which the opening ceremony was held in the Physiological Laboratory under the presidency of Dr. Leonard Hill. Professor Osler delivered an address which was divided between the praise of research and the impeachment of the University of London for not having found a way to provide a readily accessible M.D. degree for the industrious London student. Of research he said that every student should cultivate it without thought of examinations, and that he should regard it as the complement of his clinical studies and not as a thing apart. Of the University of London he declared that there was "something rotten in the State," and reminded his hearers that "the Lord helps those who help themselves." In a word, the students should organise and agitate in a constitutional manner, and then they would get their degree within a year or two. The Vice-Chancellor, who replied to Professor Osler, threw the blame on the Faculty of Medicine with its 400 teachers, which, although the University had been reconstituted for nine years, had not sent up a definite proposal on the subject that could be considered by the Senate, a quarter of whose members had medical qualifications. He supported Professor Osler, however, in his advice to the students to organise to deal with the matter. The proceedings were brought to a conclusion by the delivery, in the library, of Professor Osler's Schorstein address on the Relation of Aneurysm to Syphilis.

BRITISH RADIUM.

THE announcement that radium is to be both quarried and recovered from its ore in England must be regarded with satisfaction. We believe, however, there are still mines in Cornwall from which a comparatively rich pitchblende is sent to Germany for the extraction of its radium. The foundationstone of the radium and uranium works of the St. Ives Consolidated Mines, Ltd., and the British Radium Corporation, which are to be erected in Limehouse, was laid by Lady Ramsay on Saturday, Oct. 16th. It appears that some stimulus has been given to the enterprise by Sir William Ramsay's discovery of a process which will considerably diminish the time taken to recover radium from its ore. Hitherto the process has involved some months' working. whereas now it is stated that it can be done in as many or even less number of weeks. This is a step of considerable importance, having regard to the infinitesimal quantity of radium present in the raw material. Sir William Ramsay said that when his attention had been called to the occurrence of pitchblende in Cornwall he did not foresee that the demand for radium would be great, while he also thought that the difficulty of supplying it would be considerable. With the formation of a radium institute he felt bound to withdraw his former opinion. . The question whether subsequent investigation will show radium to be of still greater

value in medical science must remain open. So far the results had been encouraging, and the success which has attended the application of radium rays in some diseases is rapidly opening up new questions of the greatest interest. But what we may term photo-therapy is still only in its infancy, and as the analysis of radium rays proceeds it is just possible that rays of the nature of radium rays may be obtained by mechanical means, in which case we should not be so dependent upon radium. That would be an undoubted advantage, seeing what small quantities of radium are available and what labour is involved to separate them.

THE LATE PROFESSOR LOMBROSO.

Professor Cesare Lombroso, who died suddenly from heart disease on Tuesday last at his residence in Turin, had a world-wide reputation as the author of works which have greatly exercised the minds and pens of criminologists, psychologists, social reformers, and other students of human degeneracy in its various aspects. Of Jewish descent, he was born at Verona in 1835, took a medical degree at Padua, and served in the Italian campaign against Austria in 1859. His literary career commenced at a very early age, and was for more than 40 years extremely successful, although the somewhat fantastic ideas embodied in several of his works have gained but few adherents in England. His "L'Uomo Delinquente" and "L'Uomo di Genio" contain a full presentment of his anatomical, pathological, and atavistic theories of crime and genius.

A TYPHOID CUTANEOUS REACTION.

IN 1907 von Pirquet described his tuberculin cutaneous reaction, which was soon after followed by the announcement of the tuberculin conjunctival reaction by Calmette. Inspired by these discoveries Professor Chantemesse investigated the effect of the toxins of the typhoid bacillus on the conjunctiva in typhoid fever and discovered a typhoid reaction analogous to the tuberculin reaction. Calmette's reaction proved a trustworthy test for the diagnosis of tuberculosis, but in some cases the reaction proved severe and even provoked ulceration of the cornea. Hence it has been to a large extent abandoned in favour of the safer cutaneous reaction. In the University of Pennsylvania Medical Bulletin for August Dr. S. J. Deehan has described a typhoid cutaneous reaction analogous to the tuberculin cutaneous reaction which promises to be useful in the diagnosis of typhoid fever. He undertook the investigation because the dangers of the tuberculin conjunctival reaction suggested to him that the typhoid conjunctival reaction might also be dangerous. His technique was as follows. A strain of virulent typhoid bacilli was grown on agar-agar for 24 hours. The bacilli were then washed from the medium with normal saline solution and shaken up in a test-tube so as to distribute them and break up the clumps. The fluid was incubated for four days at 37.50 C. At the end of this time it became partly clear from sedimentation of the bacilli, which were more or less disintegrated. The fluid was then sterilised at 60°C. for half an hour, and centrifugalised for from two to six hours. The clear supernatant fluid was pipetted off into sterile tubes. The number of bacilli per cubic centimetre was determined by Wright's method of standardising vaccines. A solution of the strength of three billions of bacilli to the cubic centimetre was found to give the best results. The fluid was tested by cultures to ensure its sterility—a point of great importance. This fluid contained the toxin of the bacilli. The more virulent the bacilli used and the less they were modified by cultivation, the more powerful the extract. The fluid retained its strength for several weeks and then gradually grew

weaker until nearly inert. The cutaneous reaction was obtained as follows. A drop of the fluid was placed on the skin, and then with a lancet a slight abrasion was made under the drop. Only the most superficial layers of the epidermis need be removed, as it is necessary only to open the superficial lymph channels and unnecessary, and even undesirable, to draw blood. At a distance of about an inch a control abrasion should be made under a drop of normal sterile saline solution. There are three grades of positive reaction: 1. A feeble reaction, which consists of a hypersemic zone 2 to 4 millimetres in diameter, in the centre of which is a papule; the skin is slightly swollen and hard. 2. A medium reaction. The hyperæmic zone is 4 to 8 millimetres in diameter and there are numerous very prominent papules. Sometimes the skin is ædematous throughout the area. The redness may persist for hours or for one or two days. 3. A strong reaction—an intensification of the last reaction. The area of reaction is very resistant to touch and the area of hyperæmia is 2 to 3 centimetres in diameter. If the subjacent cedematous area is marked there is an appearance of urticaria. Occasionally at the points of scarification serous fluid exudes. 12 cases diagnosed clinically as typhoid fever gave a positive reaction in from 15 to 24 hours. The day of the disease on which the test was applied varied from the seventh to the twenty-second. The test did not cause the patients any annoyance or discomfort. The test was also tried in eight control cases of various diseases—heart disease, neurosis, acute gastritis, chronic bronchitis, acute rheumatism, pulmonary tuberculosis, cardiac asthma, and cancer of the uterus. In none was there the slightest evidence of a reaction. Dr. Deehan concludes that the typhoid cutaneous reaction is of considerable diagnostic value and is without danger. It was frequently obtained several days before a positive result with the Widal test could be got, and therefore in a doubtful case would enable a diagnosis to be made earlier than by this method. But its greatest value lies in the fact that it can be performed by the practitioner himself without any laboratory assistance.

THE PHARMACOLOGY OF THE LEECH BITE.

THE leech, it seems, is to take a place among those empiric remedies which in these later scientific days have been established by the discovery of a rational basis for their employment. Wiel and Boy6,1 in comparing the effect of a true leech-bite with that of the scarification made by an artificial leech, call attention to their observation that while hæmorrhage ceases soon after the removal of the latter blood continues to coze from the wound of a leech long after it has gorged itself and fallen off, in some cases for as long as 36 hours. Moreover, the clot which forms at the end of this period is soft and non-adherent, and if it be lifted off the wound bleeding may start again. A study of the blood collected from a leech-bite shows that in its method and rate of coagulation it imitates that of the blood in hæmophilia, and the likeness is completed by the effect of adding human serum, two drops of which suffice in both cases to accelerate the process of clotting. The retardation of clotting was found to vary in the blood from different leech-bites, and this variation was further shown to depend, not on the patient, but on the leech. This tallies with the observations of Haycraft, who found a substance hostile to coagulation in the head of the leech, contained apparently in certain salivary glands. This substance, as Weil and Boyé show. exercises its influence mainly, but not solely, at the spot bitten; the coagulation time of the blood from remote

parts is also increased, and recurrences of epistaxis have been recorded in persons to whom leeches had been previously applied. Again, injection of leech extract into rabbits brings about a condition of affairs which is a good imitation of hamophilia. The writers conclude with the rather ambitious statement that bleeding by means of leeches possesses all the advantages of phlebotomy without any of its drawbacks.

THE LONDON MILK-SUPPLY.

BETWEEN July 1st and Oct. 8th, 1909, 645 samples of milk sent to London railway termini from the home and western counties have been examined on behalf of the London County Council. The examination of 578 of the samples has been completed to date, with the result that 33, or 5.7 per cent., were proved to be tuberculous. Since the Council obtained powers to take samples (under their General Powers Act of 1907) 1721 samples have been taken and 1254 of these examined, 114, or 9 per cent., being proved to be tuberculous. The powers granted to the Council under the same Act to visit farms outside London have been made use of to a considerable extent. 53 farms were visited during last quarter and 2067 cows inspected, 27 of which suffered from tuberculosis of the udder. Since the Act came into operation on July 1st, 1908, 12,170 cows have been examined and 289, or 2.4 per cent., found to have tuberculous udders. The whole of this useful work in safeguarding the milk-supply of London is being done at a cost of a little more than £1000 a year.

THE IMPERIAL MALARIA CONFERENCE.

In our issue of Sept. 25th we gave an outline of the circumstances in which the Government of India had decided to convene a conference of delegates from local governments to examine a number of questions relating to malaria. This conference, which met at Simla on Oct. 11th. has now concluded its sittings and has made recommendations very much on the lines which might have been anticipated. According to the report furnished to the Times by Reuter, these recommendations have been drawn up under six main heads, of which the four first are in substance as follows: (1) The appointment by the Government of India of a scientific investigation committee for inquiry into the distribution of malaria in India, its epidemiology, and the action of quinine and other remedies : (2) the checking of existing vital statistics so as to determine the exact causes of death; (3) practical measures, including the extirpation of anopheles, drainage operations, the introduction of fish into tanks and other collections of water, and the oiling of certain collections of water; and (4) the use, sale, and distribution of quinine.

THE ENDOWMENT OF RESEARCH.

Dr. R. O. Brown of Preston has generously promised to continue for a further period of two years the pathological scholarship of £150 per annum which he has founded in connexion with the Committee for the Study of Special Diseases in Cambridge. It will be remembered that we have reviewed the bulletins of this committee dealing with its investigations upon rheumatoid arthritis, and it is noteworthy that it has elected to study one of the chronic diseases which are as a rule unduly neglected in research although they cause a far greater sum of human suffering than do the acute disorders which are so much more striking in their manifestations and more dramatic in their cure. But the chief point of interest and encouragement about the work of the Cambridge Committee is that it has largely been made possible by the generosity of an individual member of the medical

profession, and we commend this excellent example to those who are in a position to follow it, be they medical or lay. No better benefaction can be made to the commonwealth than the endowment of medical research, but although the responsible body of educated opinion in this country is on the side of truth and enlightenment such endowment is still scanty. All medical men should preach the necessity for the endowment of scientific work; it is only the lot of a few to be in a position to make gifts, but when such a one comes forward his action is doubly welcome.

RESULTS OF VARIOUS TREATMENT OF KERATOCONUS.

KERATOCONUS or conical cornea, which occurs about once in ten thousand cases of eye disease, is, we are told by Mr. J. Herbert Parsons, probably in the majority of cases a congenital affection. De Schweinitz, on the other hand, remarks that it is rarely congenital, usually developing after the age of 15 and in women. Its etiology is unknown and it has been seldom examined microscopically. By some it has been attributed to increased intraocular pressure; by others to malnutrition consequent on exhausting illness, menstrual disturbance, and chronic dyspepsia; by others to defective embryological development; and by others again to some affection of the uveal tract. The cornea when examined under the microscope has been found to be thinned near the centre, but with the membrane of Descemet unaltered. The membrane of Bowman was also thinned and wrinkled and there were spaces in the superficial layers of the epithelium. The apex of the cone is usually nebulous. In well-marked cases the conical form of the corneal protrusion is striking when the cornea is viewed laterally as is well shown in a figure by Ball. The symptoms in the early stages of slighter forms of the disease are those of astigmatism, but in the higher degrees there are headaches, pain in the eye, near sight, polyopia, and great impairment of vision. It is a slowly progressive affection, but neither ulceration nor rupture occurs. At the last Congress (1909) of the French Ophthalmological Society questions were proposed as to the best treatment of keratoconus and how long the effects lasted. M. Parisotti was charged with the duty of reporting on the subject In the course of his remarks he observed that amongst the many letters which he had received not one had made any allusion to the duration of the results obtained. Nevertheless, as he truly remarked, it is impossible to formulate with precision any judgment founded on the various modes of dealing with this condition. In an article contributed to the Recueil d'Ophtalmologie (No. 8, 1909), M. Ch. Sauvineau adduces two cases of keratoconus in both of which the material improvement resulting from the treatment has been maintained, in one case for 12 years and in the other for 15 years. In the first case the patient, aged 31 years, had long been under the care of M. Panas, who had treated him with myotics and compress bandage. An iridectomy was performed at the infero-internal segment of the iris, the artificial publi being narrow and at the lower part of the iris. The improvement in vision was so great that to avoid the confusion that resulted from the entrance of light through the natural pupil the most prominent point of the cornea was lightly touched with the galvano-cautery twice. Finally, the opacity was tattooed with such benefit that the patient was able to discharge his duties as a civil engineer. The second case was treated successfully with glasses. In the same journal is a note by Dr. Antonelli on the case of a young woman, aged 34 years, who was materially assisted by cylinders. In addition, as she particularly enjoyed the opera, he had specially ground for her a pair of

¹ Modern Ophthalmology, p. 344.

contact glasses (verres à contact), which, as soon as she reached her box, she was able, after inserting a cocaine tablet, to slip under the lids, and bear without discomfort for the whole evening. In addition, she applied pilocarpine night and morning, followed by a compressive bandage. Examinations have been made from time to time with test-types and have shown no increase in the development of the disease. Dr. Antonelli questions the advantage of the hydrodiascope of Lohnstein.

A TELEGRAM from the Governor of Mauritius to the Secretary of State for the Colonies stated that 20 cases of plague with 16 deaths were reported during the week ending Oct. 14th.

SOME CONSIDERATIONS OF MEDICAL EDUCATION.

I.

A Bird's-eye View of the Present Curriculum. - The Supervision of the General Medical Council. - The Merits of the

In this short series of chapters on medical education many things will be said which have been said before and said by many people. But the risk of appearing to repeat old cries must be taken if the difficult subject of medical education is to be treated of at all fully and placed before the reader in such a way that he can appreciate the questions at issue even though he have not given them much thought before. And, alas, there are many medical men who are only now beginning to wake up to the fact that the education of our students is of enormous importance.

The ground can be best cleared by giving a bird's-eve view of the curriculum so far as it is common to all the medical schools and educational bodies through which a place on the official roll can be obtained, while showing at the same time that this curriculum is supervised by the General Medical Council in such a way that whatever the machinery employed the result should be to turn out an adequately educated man. Every year the medical journals publish educational issues in which the salient circumstances of all the medical schools are fully set out-the names of the professors and lecturers are given, the fees to be paid by the students, and the prizes and scholarships to be gained. In the Students' Number of THE LANCET there will also be found full particulars of the ancillary medical schools where a certain part of the medical curriculum can be taken out, as well as a summary of the course to be pursued by students desirous of a commission in one of the services or of an opportunity to serve under Government. None of this information need be repeated here, but a few generalisations from it and from the annual reports of the General Medical Council and of the various medical schools may be given, both as an indication to show the present state of medical education and as a standpoint whence we may look a little into the future and forecast what may happen and express hopes as to what should happen—the processes being not necessarily identical.

The position of medical education in Great Britain and Ireland at the present day is in a similar plight to the professional position; there is much that calls for criticism and much that needs reform, but the story is one of progress. Medical education is in many particulars open to amendment, but the principles, as laid down by the statutory educational bodies and endorsed by the General Medical Council, appointed by Act of Parliament as the coordinating authority, are sound, and this point is one that cannot be too much insisted upon in view of the frequent detraction from the work of the General Medical Council. The desire of the

General Medical Council ever since its institution has been to secure an adequate curriculum for the medical student, so that the medical practitioners of England, Scotland, and Ireland, through whatever qualifying body as a medium they may enter the medical profession, should discharge their duties in accordance with a due, even a high, standard of efficiency. As this has also been the aim of the variousqualifying bodies, the great majority of which were in existence years before the institution of the General Medical Council, the educational work of the Council as a standardising authority has been simplified. The Council as the central educational authority has had to do work in most instances in directions in which the various bodies to whom medical education is in detail committed are anxious to work. The Council, however, has recently been confronted with difficulties mainly arising from the general development of medical knowledge and the consequent increase of subjects for which space has to be found in the student's curriculum, but due also to a want of complete accord in the aspirations of all the qualifying bodies and to the special circumstances which surround the medical student at the London schools.1 These difficulties are very real, as further consideration of them will show.

The scheme which the various qualifying bodies have adopted by a sort of general consensus of opinion, and whichis approved of by the General Medical Council, may be summarised as follows. Firstly, the student must pass a preliminary examination which is not of a stringent character. Secondly, he must enter upon a five years' curriculum from the date of passing that examination, during which time he must submit himself to three tests-a preliminary scientific examination, an intermediate examination, and a final The preliminary scientific examination, the examination. subjects of which are chemistry, botany, biology, and physics—the subjects which are sometimes termed ancillary should be passed at the end of the first year; the intermediate examination, the subjects of which are anatomy and physiology, should be passed at the end of the thirdyear; the final examination, the subjects of which are medicine, surgery, and obstetric medicine, should be passed at the end of the fifth year. From this bald synopsis of the general medical curriculum the aim of the education authorities can be gathered. The first year of the medical student's curriculum should be devoted to the more or lesselementary study of the sciences which he will later find are necessary to the comprehension of medicine—the ancillary sciences; the next two years should see him in the dissecting-room and the physiological laboratory learning toappreciate the shapes, dispositions, relations, and functions of the normal human body, as the only method of detecting and understanding any lapses into disease or pathological conditions due to injury; and the last two years of the curriculum will be spent in the wards and out-patient departments of a hospital.2 Such is the ideal division of the medical student's time during a compulsory course of five years' duration; but the average time taken in accomplishing that course is nearer seven than five years, and every development in scientific medicine threatens, unless the seriousness of the situation is recognised, to increase this already considerable time.

The duration of the medical curriculum has been extended in obedience to the vastly greater scientific and professional equipment that is now required of the medical practitioner

¹ Mr. F. C. Wallis, the Dean of the Charing Cross Medical School, has recently called attention to this matter in a vigorous speech at the opening of the new medical session, and his words have received considerable attention in the daily press. (See THE LANGET, Oct. 9th, p. 1093.)

² Dr. Samuel West, in his Presidential Address to the Medical Society of the relation of the properties of the propertie

of London, included an excellent synoptical table showing the relati of the ancillary sciences to medicine, THE LANGET, Oct. 18th, p. 1121.

in whatever branch of medicine he may be called upon to practise. Many years ago, nearly 30, it was extended from three years to four, while a change made 12 years ago extended it from four years to five. Each change necessitated a rearrangement of their examinations upon the examining bodies, and the result is that at the present moment a great similarity appears in the educational course of all of them, every student having the same subjects to read and to acquire practically in the same space of time. This uniformity may be insisted upon a little, for it is exactly what would not be expected to exist where over 20 educational institutions, having their homes in different countries and drawing their clientèle from different classes, compete against each other for the patronage of the student requiring a qualification. The fact that at the present time, under a system in which many faults of detail can be found, a high general level of education is maintained, making down-grade competition improbable, is very striking. And it has a forcible bearing upon propositions for reform because it suggests that the existing condition is a sound one and that nothing is required save to simplify it-(1) by removal of the anomalies that are due to its growth into a whole from many separate directions, and (2) by resistance to unnecessary developments undertaken with the vain hope of examining students, whose season of acquisition must be limited, in all the unlimited extensions of modern medicine.

The scheme of medical education in England, Scotland, and Ireland to-day is very nearly uniform. The preliminary examinations are easy, perhaps too easy, the intermediates and finals are thorough. The entrance to practice is better guarded at one door than at another, but everywhere the curriculum is well devised and may turn out good men. Moreover, the various educational bodies are zealously and constantly watched by the General Medical Council, which is never accused of being supine in respect of educational supervision. The final examinations of all the universities and corporations are tested periodically by the visitors and inspectors of the Council, and from the reports which these officials make from time to time to the Council a very good idea of the present state of medical education in the various centres can be obtained. The Apothecaries' Hall of Dublin, which turns out now very few qualified men, is the only body which has recently taken up the attitude that these inspections are derogatory to the dignity of a corporation, but it is necessary for the Council to be on the look out for any down-grade competition.

The process of inspection is as simple as it is drastic. The General Medical Council deputes a visitor, a member of the Council, and an inspector, not a member of the Council, who attend from time to time as the Council directs at the qualifying examinations of particular bedies. The visitor and inspector can attend together or separately as they are instructed, and can make joint or several reports. They read some of the candidates' papers and make their own marks upon them, which they afterwards compare with the marks made by the examiners. They listen to the clinical and oral examinations of the candidates and take note of the style of questions that are asked and the style of answer that is accepted. They observe the facilities provided for convenient examination of the candidates, the supply of instruments and pathological specimens, the precautions against copying, the amount of time allotted to the examination viva voer of a candidate or the answering of a written question. And finally, they attend at the adjudication of the examiners upon the candidates' merits. In this thorough way they can see if the examination is kept at a proper standard and if the student obtains fair play; and there is no doubt that the criticisms of the Council's delegates, though sometimes resented by the criticised educational body, have been most valuable in maintaining Chater Charlton, D.M.D. Harvard, Harvard University and

a high general standard of medical training. The supervision of the Council is very real and minute, and the strictures which have been passed in some directions show that all qualifying bodies, whatever their position, are treated with the same respect, while the value of the work is proved by the fact that an indifferent report on one occasion is observed to be followed usually by a good report on the next occasion.

Our medical curriculum has, then, these things to be said for it. It is carefully devised and thorough—in comparison with that of other countries it stands well; it is uniform in essentials, despite the anomalies that are due to the fact that degrees and diplomas can be given by such widely different bodies; an independent and powerful Government department, through the General Medical Council, watches over the curriculum and the examinations which close it, to ensure the maintenance of a certain standard. The precautions taken by the General Medical Council with regard to the examinations are all directed towards making the tests fair, towards eliminating the element of chance as far as possible from them, and towards the practical equipment of the medical man for his public duties. There is plenty of room for improvement in the general educational scheme, but as far as it goes it is satisfactory. All medical men must submit themselves to a carefully standardised trial before they win a place upon the official roll of their profession, and so become legally qualified to minister to the public needs.

But because the medical curriculum has so many pleasant things that can be said about it we must not be blind to the fact that the difficulties of medical education are increasing, that the burdens alike of teacher and taught are now very heavy, and that there is an amount of wasted effort which is tragic.

(To be continued.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MRETING OF COUNCIL.

A QUARTERLY meeting of the Council was held on Oct. 14th, Mr. H. T. BUTLIN, the President, being in the chair.

The SECRETARY reported the death on Oct. 1st, at the age of 76 years, of Sir Thomas Smith, Bart., K.C.V.O., Honorary Serjeant-Surgeon to the King, past vice-president and past member of the Council. It was resolved-

That the Council do hereby record their deep regret at the death of Sir Thomas Smith, Bart., K.C.V.O., whom they highly esteemed for his valuable services to the College and whose personal character made him an object of affection to all his colleagues. The Council do also deather to express their very sincere sympathy at the loss which his family have sustained by his death.

The SECRETARY also reported the death on Oct. 5th of Dr. William Rivers Pollock, examiner in midwifery under the Conjoint Examining Board.

The PRESIDENT stated that the vacant examinership in midwifery would be filled up at the meeting of the Council in December.

The diplomas of Fellow or Member were conferred upon the following gentlemen, who have complied with the respective requirements, viz.:—Diploma of Fellow: Albert Edward Mortimer Woolf, M.R.C.S., L.R.C.P., B.C. Cantab., Cambridge University and London Hospital, Diploma of Member: Enoch Turner Atkinson, M.D., M.S. Toronto, Toronto University and Middlesex Hospital; Lancelot Bromley, B.A. Cantab., Cambridge University and Guy's Hospital; Isaac Marcus Edis, London Hospital; Patrick Clive Fowell, B.A. Oxon., Oxford University and St. Bartholomew's Hospital; Harold Edward Jeffreys, M.B., B.S. New Zealand, New Zealand University and Middlesex Hospital; and Charles Dudley Roberts, Guy's Hospital.

The Licence in Dental Surgery was conferred upon Percie

Guy's Hospital; Linton Albert Ramsey Fennell, Middlesex and Royal Dental Hospitals; and Philip Reginald Helyar, Guy's Hospital.

Sir Henry Morris was re-elected for three years a member of the committee of management.

A report was read from the President and Vice-Presidents on the proposed celebration of the jubilee of the Grant of the Charter enabling the College to confer Diplomas in Dental Surgery.

It was resolved in accordance with this report that the celebration should take the form of a dinner given by the College to the leading members of the dental profession. The date of the dinner will be Thursday, Dec. 2nd, and it will be given in the library of the College.

Mr. R. Clement Lucas was elected for three years the representative of the College on the court of governors of the University of Sheffield.

A letter was read from the joint secretaries to the Royal Commission of University Education in London stating that in the early part of next year the Royal Commission will be prepared to receive information regarding the view of the Royal College of Surgeons of England upon questions connected with medical education in London, and that as soon after the close of this year as possible the Commission would like to have a statement of the nature and scope of the evidence proposed to be given and the names of the witnesses who will represent the College. - The matter was referred to a committee.

Mr. EDMUND OWEN, on behalf of the Committee on the Annual Report of the Council, submitted a draft copy of the report which is to be presented to the Fellows and Members at the annual meeting on Thursday, Nov. 18th.—The report was approved and adopted.

THE ANNUAL REPORT OF THE COUNCIL.

The report contains a record of the work done in the various departments of the College during the collegiate year ending on August lat-last. With regard to the proposed combination of the Royal Colleges of Physicians and Surgeons with the University of London (mentioned

ments of the College during the collegiate year ending on August 1st last. With regard to the proposed combination of the Royal Colleges of Physicians and Surgeons with the University of London (mentioned in the last annual report) to consider a scheme for establishing a system of Conjoint Examinations in accordance with Statute 123 of the University, the delegates appointed by the Royal Colleges in reference to the matter state that, taking into consideration the provisions of the statute, the existing conditions of medical education in the metropolis and the undoubted demand for a degree in Medicine which shall be more accessible to the average London medical student, and assuming the existence of a general desire on the part of the University, the Royal Colleges, and the medical schools of London to unite in a concerted effort to provide such a degree, they, the delegates, are of opinion that there should be little difficulty in arriving at an equitable and advantageous solution of the problem.

In considering the scheme the delegates state that they have taken as a basis of their deliberations the following principles: (a) That the University should rotain all its existing rights as to the granting of degrees, but should consent to exercise them as regards pass degrees conjointly with the Royal Colleges so far as those students are concerned who shall have spent not less than four years in study at London medical schools and hospitals, and who shall have complied with such conditions as the University and the Royal Colleges may determine. (b) That the Royal Colleges should retain all their existing rights to grant diplomas to those who are not eligible under the foregoing conditions, or to those who do not desire to come under such conditions. (c) That the Royal Colleges should be associated with the University in conducting the Preliminary Scientific, Intermediate, and Final Examinations for the Pass Degree (M.B., B.S., M.D.). The delegates believe that this arrangement will secure the following advantages

prepared to bring forward a working scheme for carrying the proposal into effect.

Since the reception of the report of the delegates a Royal Commission on University Education in London has been appointed, and the College will be afforded the opportunity of giving evidence before the Commissioners at some date in 1910. In the meantime the Royal Colleges have approached the University of London and the delegates of the Royal Colleges have met representatives of the University and placed the proposed scheme for combination before them.

With regard to the question of the administration of anæsthetics and in answer to a letter received from the General Medical Council inquiring how far the College had given effect to a recommendation of that Council as to requiring students to produce evidence of having received practical instruction in the administration of anæsthetics, the Council of the College replied that the desirability of making practical instruction in the administration of anæsthetics a compulsory part of the medical curriculum was recognised by the College in 1901, and that, in conjunction with the Royal College of Physicians, a regulation was adopted in that year requiring a candidate before admission to the Final Examination to produce certificate "of having received at a recognised medical school

and hospital, instruction in the administration of anæsthetics to the satisfaction of his teachers," and that, moreover, questions on the subject are from time to time put to candidates by the examiners of the College. Upon the recommendation of the Board of Examiners in dental surgery it has been determined to also require that candidates for the Licence in Dental Surgery of the College shall be instructed in the administration of anesthetics, and all candidates for the Licence who enter at a recognised dental hospital or school are now required to produced a certificate "of having attended at a recognised dental hospital and school a course of practical instruction in the administration of such anæsthetics as are in common use in dental surgery."

With reference to the admission of women to the examinations for the College diplomas the Council state that in accordance with the requirements of the Charter of 1843 the new by-law in reference thereto has been submitted to the Secretary of State for Home Affairs for sanction and ratification.

nas been submitted to the secretary of State for Home Affairs for sanction and ratification.

The conditions of the transfer of the museum of the Odontological Section of the Royal Society of Medicine, which has been offered to, and accepted by, the College as a trust, are published in the report. The transference of this important collection represents one of the largest and most valuable additions ever made to the museum of the College. The collection contains about 5000 specimens arranged in 13 mahogany cases. At the present time the College collection of odontological specimens, many of them being those used by Hunter in the preparation of his monograph on the teeth, are shown in several sections of the museum. It is proposed that these should be brought together and added to the collection now entrusted to the College, the whole to be arranged in a commodious and accessible room in the basement of the museum, to be known as the "Odontological Room." The addition of this collection, although it will entail a considerable expenditure of both money and labour, will place the museum in possession of one of the most valuable odontological collections in the world.

With research to the world of the museum of the museum to the collection of the museum in the collection of the museum in the world.

expenditure of both money and labour, will place the museum in possession of one of the most valuable odontological collections in the world.

With regard to the work in the museum for the past year the chief place must be given to the alterations which have been and are being effected in the system of cataloguing and labelling its contents. After a prolonged inquiry the Museum Committee recommended the adoption of a card form of catalogue, which is considered to have many advantages over the book form at present in use. It is estimated that the new system of cataloguing will involve the preparation of 250,000 cards. Four cabinets have been designed to contain the cards and have been placed in the entrance hall of the museum. The total number of visitors to the museum for the year was 12,862, a slight increase in the number for the previous years. Special arrangements were made for the reception of two large parties of French physicians, whilst several scientists from abroad have visited the museum for the purpose of research. Altogether 138 men have visited the museum in connexion with scientific inquiries which are being carried out by them. On Saturday afternoons the museum was kept open on 28 occasions for 82 classes, 17 of which (305 students) were connected with evening science and art centres of the London County Council. The remaining 65 classes were composed of ambulance and polytechnic students (1182 in number), and were conducted round the museum by their teachers, many of whom are medical men. A series of 12 demonstrations explanatory of the contents of the museum were given during the year by, the conservator and the nathological curator. The demonstrations explanatory of the contents of the museum were given during the year by, the conservator and the nathological curator. The demonstrations explanatory of the contents of the museum were given during the year by, the conservator and medical men. A series of 12 demonstrations explanatory of the contents of the museum were given during the year by, the conservator and the pathological curator. The demonstrations were well attended and have been the means of extending and improving the various sections of the museum on which they were given. During the past year the supply of books and journals has been well kept up, and many valuable donations have been made to the library. In addition to these donations five interesting Hunterian papers, including Clift's own account of his apprenticeship to Hunter, MS, and other biographical data, and the MS. of Mrs. Ann Hunter's proposed Epitaph on Hunter have been presented.

The purchase of the Examination Hall by the Institution of

of bis apprenticeship to Hunter, MS. and other biographical data, and the MS. of Mrs. Ann Hunter's proposed Epitaph on Hunter have been presented.

The purchase of the Examination Hall by the Institution of Electrical Engineers has been completed, and arrangements have been made whereby the examinations of the Royal Colleges of Physicians and Surgeons will continue to be conducted at the Examination Hall for some time, sufficient accommodation having been leased from the institution for three years from June 1st last, with option of renewal on a yearly tenancy. A site for a new examination hall has been acquired in Queen-square, Bloomsbury, comprising four houses, the freeholds and leaseholds of which the Royal Colleges have agreed to purchase for £23,000. A sum of £24,512 was realised by the College from the sale of the Examination Hall buildings and lease. The original cost to the College of the buildings amounted to £30,251, and when from this has been deducted £1736, the share of the sinking fund transferred to the College, the loss on the original cest only amounts to £400. This is considered a satisfactory price as allowance must be made for depreciation of the buildings during some 22 years.

Regarding the finances of the College the income for the past year amounts to £25,401, an increase of £427 on that of the previous year. There is an increase of £109 in the receipts from the Conjoint Examining Board in respect of the Membership, and of £70 in respect of the Diploma in Public Health, as regards the share apportioned to the College. There is also an increase of £189 in the receipts from the Conjoint Examining Board in respect of the Membership, and of £70 in respect of the Diploma in Public Health, as regards the share apportioned to the College. There is also an increase of £189 in the receipts from the Conjoint Examinations there are small increases, whilst an increase of £171 is also shown in the general working expenses of the College. The most noticeable increase, however, occurs under the specia

A Somerset Centenarian —Miss Hensley of Bath celebrated the 104th anniversary of her birthday on Oct. 16th, and received a congratulatory telegram from the

THE CRIPPLES' HOME AND COLLEGE, ALTON.

On Oct. 16th Sir William Treloar entertained a large party of friends and subscribers at the Lord Mayor Treloar's Cripples' Home and Hospital which he has founded at Alton in Hampshire, where it occupies the buildings originally erected as the Princess Louise Military Hospital. Between 200 and 300 people attended in spite of rain, the gathering including several members of the honorary medical staff. special train was run from Waterloo, and upon arrival the visitors were conducted round the carpenters', leather-bag making, and tailoring workshops, the power-house, laundry, chapel, and college. The buildings, which are situated in an estate of some 70 acres in a pleasant part of Hampshire, were seen to consist of wooden pavilions on brick piles, most of the wards being linked up by covered corridors. Luncheon was served in the gymnasium, and Sir William Treloar, in giving an account of the work, told his audience that there were 60 cripples learning trades in the college, and 200 cases of active bone tuberculosis in children under 12 years of age undergoing treatment in the hospital. Speeches in support of the work of the institution were also made by Sir Melvill Beachcroft, Sir Edward Clarke, and Sir Ernest Flower, and then the guests were conducted round the wards by Mr. H. J. Gauvain, the medical superintendent, who was responsible for the original arrangements of the hospital wards, and has charge of their administration. Our representative, who is indebted to Mr. Gauvain for supplying many of the following details of the work of the Alton Hospital and Home, was given an opportunity of seeing some of the admirable results which have been obtained there by careful and efficient splinting and the subsequent use of a plaster jacket.

It has long been recognised by English surgeons that treatment of children suffering from tubercular bone lesions in the out-patient department of our hospitals is terribly unsatisfactory. The beds of most general hospitals are in so great demand that usually they are not available for the necessarily prolonged treatment required to ensure a cure, and consequently are, as a rule, only open to the admission of these children when urgent symptoms render radical treatment imperative. The Cripples' Home and Hospital has been designed to remedy this defect. It is essentially an institution for active treatment and not simply an asylum. Children admitted to the Home are detained as long as they can be benefited by treatment, which means in the great majority of cases until they are apparently cured. It is particularly gratifying to record that not only has the need of such an institution been recognised, but its existence is fully appreciated by the medical profession. No patient is admitted unless his application form for admission has been signed by a surgeon of a hospital and approved by the Alton medical board. This medical board, the members of which were nominated by the Presidents of the Royal College of Physicians of London and the Royal College of Surgeons of England, is under the chairmanship of Mr. John H. Morgan, C.V.O., and is composed of physicians and surgeons selected from the visiting staffs of leading London hospitals. One or more of the members of this board visit the institution periodically to inspect the Home and to advise the medical superintendent in the treatment of cases, and the board meets monthly in London to consider his report and to assist in every way in its power.

All patients on admission are kept in quarantine for a fortnight in a separate glass cubicle in one of the observation wards. The clothes in which the patients come to the Home are at once sterilised, and every possible precaution is taken to prevent the introduction or spread of infectious disease. During the time the child is in quarantine his case is carefully investigated, notes are written, his tastes studied, his diet regulated, and such splints and appliances as are requisite are made. During this period he is also gradually acclimatised and taught to withstand the rigors of an open-air life. Very great stress is laid upon adequate mechanical treatment. Everything possible is done to prevent deformity, and

where that already exists to prevent its increase. of efficient mechanical treatment is especially shown in many of the spinal cases under treatment at Alton. The splints are made at a trifling cost by the carpenter under the supervision of the medical superintendent who adapts them to each case individually. Great attention is paid to diet. The appetites of tuberculous children are notoriously capricious, and every endeavour is made to improve their powers of digestion and assimilation. This trouble is amply repaid by the obvious improvement effected in their general health by good food combined with open air. Drugs are employed where indicated, but occupy only a subsidiary part in the treatment. Vaccine therapy has not been neglected. There exists at this Home an excellent field for careful research in the use of tuberculin and vaccines generally, and it is much to be hoped that funds will be forthcoming to equip a laboratory and provide an efficient clinical pathologist.

Bier's hyperæmic treatment is also employed in suitable cases, but in the medical superintendent's experience the most valuable curative agent is proper mechanical treatment under the best hygienic conditions. Mr. Gauvain treats nearly all tuberculous abscesses by aspiration under strict aseptic precautions and finds the results much better than those of operation, which so often ends in sinus formation and septic infection. No operation, except in cases of emergency, is performed at the Home without the surgeon who sent the case being notified and being given the opportunity of having the patient returned to him or coming to the Home to operate himself if he prefers. We are not surprised to learn that the surgeon almost invariably prefers the operation to be performed in the Home.

Every endeavour is made to reproduce the conditions of home life rather than the atmosphere of a formal institution. Whilst no rudeness or lack of reasonable discipline is tolerated, yet every child is made to consider that he or she is a member of a very happy family. During the summer those who are capable of being benefited attend the forest open-air school, which is designed on the lines of the forest school at Charlottenburg. Here they work under ideal conditions. But work is a secondary desideratum, the cure of the child being the first aim, and there are no rigid rules for compulsory attendance. In the winter the children are taught in the winter schoolroom or in the wards. Under these carefully thought out conditions it is not surprising that the progress of the children has been good. In some 300 children who have been under treatment two deaths only have occurred, and both have been due to tuberculous meningitis.

The College is designed for a different purpose altogether. Here boys, whose ages range from 14 to 18 years, crippled from any condition whatever, but nevertheless capable of being taught a trade, are admitted for treatment and training. They include lads who have lost one or both legs as a result of accident or disease, sufferers from club-foot, scoliosis, infantile paralysis, old but quiescent tuberculous disease, &c. The primary object here is the training of the youth under medical supervision in healthy surroundings where also a good moral tone can be ensured. The trade which the boy shall adopt is decided in consultation with the college master. Boys who would be especially benefited by an open-air life learn poultry-farming or horticulture. Other lads are taught leather-working, cobbling, or tailoring under skilled instructors. The majority work in the leather shop, as this trade has been found best adapted for their condition, and it is anticipated that on leaving the college little difficulty will be experienced by them in earning their A possible extension of this work will be the establishment of a self-supporting labour colony later. During his period of training the general health of the cripple is improved by every possible means, and where feasible endeavours are made to correct or reduce existing deformity by operative or other measures. All lads capable of benefiting by it are drilled, and their drills are performed with extraordinary zest and smartness. Lads suffering from scoliosis and other conditions are instructed in special exercises designed to lessen their deformity, and the supervision maintained enables the exercises to be systematically performed with obviously beneficial results. The boys are encouraged in games but have plenty of other occupations, as they do their own domestic work, mend their own clothes and boots, and keep their quarters thoroughly clean.

SCARLET FEVER AND MILK IN THE THAMES VALLEY.

THE public health committee of the London County Council has issued a further report with reference to an outbreak of scarlet fever which occurred last June amongst over 400 people in London and Surrey who had consumed milk from a particular company. The matter was referred to in our columns at the time.

A joint inquiry into the circumstances of the outbreak was undertaken by Dr. W. H. Hamer and Dr. T. Henry Jones, who had the help of Dr. Mervyn H. Gordon as bacteriologist. Assistance was also rendered by the medical officers of the affected districts and by the officers of the milk company. Sir Shirley Murphy, medical officer to the London County Council, commenting on this investigation, states that no reasonable doubt can be entertained that the milk of a particular farm was responsible for the occurrences of the scarlet fever in the two counties, and interest centres in the question how this particular milk acquired the ability to infect those who consumed it. In the past two hypotheses of milk infection have been discussed, the one that the milk acquired its infective property from a human source, that it was, in fact, infected by the milker or by some other person suffering from scarlet fever; the other, that milk was infected by some condition of a cow or cows. It has been observed on former occasions that inquiry has failed to demonstrate that human agency has been responsible for the infective condition of the milk; such inquiry has often shown that even when one or more persons engaged on the farm have suffered from scarlet fever the dates of their infection have been subsequent to the dates of infection of the consumers of the milk—in fact, that the milkers suffered, as other persons, from consumption of the milk. So in the outbreak investigated by Dr. Hamer and Dr. Jones it was found that scarlet fever did occur in the family of a milker, but that the evidence in connexion with this occurrence could not be regarded as affording explanation of the infection of the milk by human agency, while it distinctly suggested that the milk was infective before leaving the farm. Careful inquiry in the neighbourhood of the farm failed to yield any evidence of the existence of a human source of infection of the milk.

Sir Shirley Murphy points out that in similar circumstances Sir William Power, when investigating in 1882 an outbreak of scarlet fever in certain London districts, made the suggestion that inasmuch as "there is one sort of relation between scarlatina and accidents of the puerperal state another sort of relation becomes comparatively easy of belief," in fact, that "if scarlatina in man have other animal source than human source, it may be that one such source is the cow that has recently calved, a cow either not at all ill (except for her parturition) or not so obviously ill as to prevent her milk being used for human consumption." suggestion thus tentatively made in 1882 assumed large importance upon the demonstration by Sir William Power in 1885 of the bovine origin of scarlet fever occurring in persons consuming milk from a Hendon farm, the cows at which were affected with an eruption of the teats and udder. A similar development of scarlet fever in man, associated with the consumption of the milk of similarly affected newly calved oows, or cows infected from such newly calved cows, has been observed in a number of instances since that date. In London in 1892 and again in 1894 and 1902, considerable prevalences of scarlet fever due to infected milk were strongly suspected to have been of bovine origin. In the present instance a like possibility was naturally entertained, and it has been found possible by study of the farm operations in minute detail to show that just at the time when the milk first began to show infectious property, there was added to it the milk of three recently calved cows, the calf of one of which had died after being suckled by the cow for four or five days. These circumstances, together with the fact that the three cows mentioned and other cows at the farm showed at the time of the inquiry appearances upon their teats and udders suggestive of "Hendon disease," render it probable that a morbid condition of the cow was responsible for the subsequent human illness.

Sir Shirley Murphy remarks, in conclusion, that from the administrative side it deserves to be noted how, with the cordial assistance of the manager and secretary of the company, whose action deserves recognition, early localisation of the source of the mischief was possible. This was due to the system of record of distribution of milk maintained by the company, a system which had proved in this case to be of value alike to the public and the company.

At the meeting of the council it was decided to place the

At the meeting of the council it was decided to place the detailed account of the investigations on sale, but not before Mr. Easton had objected to the responsibility for the outbreak being fixed on the cow. He said it had been decided by the highest bacteriological authorities that scarlet fever was incapable of transmission from a cow to an infant, and inquired if the possibility of infection having been derived from railway trucks had been looked into. In his view it would create needless alarm if the report was published, and he moved the reference back.

The proposal found no seconder, and therefore fell through.

MEDICINE AND THE LAW.

Unqualified Dentistry and the Public.

THE recent trial in which Mr. G. H. Hawthorne, a baker at Cricklewood, sued the London Hygienic Institute, Oxfordstreet, for personal injuries caused by the negligent extraction of 22 of his teeth illustrates most of the evils arising out of that unqualified practice of medicine and dentistry which the law permits, and it might serve as a warning to all foolish and credulous persons if they were capable of assimilating and applying its lessons. This class of persons, however, appears to be inexhaustible alike in numbers and in credulity, and the example of Mr. Hawthorne and his teeth will probably pass unnoticed or will soon be forgotten. The victim in this case did not consult the defendants upon his own initiative, but was called upon by one of their canvassers, from which it will be easy to observe the business advantages enjoyed by the unqualified person over those whom the ethics of an honourable profession do not permit to employ agents and canvassers. The arrangement was made with the canvasser that Mr. Hawthorne should have his teeth attended to for £3 15s., paid in weekly instalments of 7s. 6d., and one payment was made before he went for the first time to the institute. Once there his business was quickly disposed of by an operator, who afterwards admitted in the witness-box that he had no medical or dental qualifications. This gentleman began by pulling out four or five teeth, when he was remonstrated with by the patient, but he proceeded with his task and ended by extracting 22 teeth at a single sitting. Apparently an anæsthetic containing 1 per cent. of hydrochloride of cocaine was used, but the plaintiff denied that it effectively prevented him from feeling what was being done to him, and he declared that he screamed with pain. There was some denial of this on the part of the defence, but there was no doubt that after washing his mouth out with whisky at a public-house, on the advice of the operator, he went home, and that there, owing to faintness and hæmorrhage, he had to call in a medical man, while afterwards a qualified dentist attended him and removed 14 stumps which had been left behind in his jaws. Those who are inclined to visit such places as the Hygienic Institute will observe that not only did Mr. Hawthorne suffer considerable physical pain and inconvenience, but that he had to pay medical and dental fees necessitated by the treatment he had received amounting to nearly £10, and that he estimated his further loss in wages at £8 10s. They may also reflect that the medical witness who attended Mr. Hawthorne when he returned from the institute deposed that his condition was such that, without medical attention, death might well have been expected to supervene. We need not discuss the evidence in detail, and we can leave such testimony as was laid before the jury on behalf of the defendants for the consideration of those who care to study it. They are not likely, whoever they may be, to blame the jury for disregarding it, and for finding a verdict for the plaintiff. Hawthorne, therefore, was nominally successful, and for the time being the London Hygienic Institute will suffer, but the damages were assessed at no more than £50. Mr. Hawthorne seems, therefore, to have endured pain, to have

suffered anxiety and pecuniary loss, even to have had his suffered anxiety and pecuniary loss, even to have had his life endangered, only to be laughed at in court and to be consoled with a sum of money which cannot have left any appreciable surplus after the payment of his necessary expenses in the action. With regard to the law Mr. Justice Bray, who certainly did not err on the side of sympathy with the plaintiff, ruled that the agreement to extract the teeth did not imply any contract to employ for the purpose a gualified person in the contract to employ for the purpose a qualified person in the sense that he should have a legal qualification for the practice of dentistry. In summing up he defined the contract entered into as one to use due care and skill in selecting what teeth were to be extracted and in extracting them, and to decide how many were to be extracted at a time; not to put the patient to unnecessary suffering, and to do properly what had to be done. The obligation was not to provide a registered dentist, but one of sufficient skill. In all this Mr. Justice Bray may be, and probably is, from a legal point of view, perfectly right. The patient in such a case is at the mercy of those who need only select to operate upon him a person of "sufficient skill." What constitutes "sufficient skill" in such a connexion is to be decided by a jury afterwards in those cases in which patients complain of ill-usage. In those in which patients do not complain we are asked to assume that there has been 'sufficient skill," although it may be merely the brute force of a man who is strong enough to pull out as many teeth as his patient is willing to part with, and who manages to do so without any immediate result of an obviously serious character. Medical practitioners and dentists are popularly supposed to advocate the suppression of unqualified practice from a desire to protect their own profits from the intrusion of dangerous rivals. The case under discussion, however, hardly points that way. It is an instance, among many, of the unqualified person providing lucrative work for the qualified in repairing the damage done by ignorance. It was the Cricklewood baker alone who suffered physically and pecuniarily, and it is for members of the public such as he and not for medical men or dentists that greater protection than the law now affords is urgently needed upon public grounds and not in the interest of any profession.

Public Bealth.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

City of Bristol.—The population of this city is now estimated at 372,785, no insignificant portion of the recent increase having been brought about by means of borough extensions. Dr. D. S. Davies furnishes in his current report some figures showing the differences in the fatality-rate of scarlet fever to-day as compared with 40 years ago. In 1863 and 1864 no fewer than 1100 deaths from scarlet fever occurred. In 1869 and 1870 there were over 900 deaths; in 1875 and 1876 over 700, and in 1880 and 1881 nearly 400, while in 1886 and 1887 there were 300 deaths. The next epidemic was in 1896, with 59 deaths, and in 1900 there was a larger epidemic, with 39 deaths, followed in 1901 with was a larger epidemic, with 39 deaths, followed in 1901 with a still larger epidemic, yielding only 36 deaths. In 1902 the deaths rose to 66. Dr. Davies points out that if in 1908 there had been a similar loss in regard to population as there was in the year 1863 there would have been 2000 deaths instead of only 10. It is very difficult, as he observes, to explain satisfactorily this change of type which has characterised scarlet fever within recent years. In all probability part of it may within recent years. In all probability part of it may be due to the removal to the isolation hospitals of cases which, by being overcrowded at home, might have added to them a septic element which would increase the fatality-rate of the disease. But there is also the consideration that there is evidence pointing to the fact that the mild type of scarlet fever which now prevails is a common feature in all countries, whether or not they are provided with isolation hospitals. Dr. Davies, in discussing the behaviour of enteric fever in Bristol, makes some very instructive observations upon "carrier" cases of this disease and, inter alia, he furnishes the later history of the wellknown Brentry woman who had apparently been the cause of numerous cases of enteric fever since her own attack in 1901,

and who, in the spring of 1908, seems to have infected herself. Subsequent to this she was regarded as having infected three other persons. In a second instance of an enteric fever "carrier" the woman, who contracted a slight attack of enteric fever in the autumn of 1907, apparently gave the disease to four of her five children in June, 1908, although she was at that time in excellent health. These although she was at that time in excellent health. cases led to an investigation into the whole subject of 'carrier' cases by Dr. Davies and Professor I. Walker Hall, who have presented an interim report to the town council on the subject, which, to a large extent, was summarised in our columns on Nov. 28th, 1908. Dr. Davies also embodies in the report before us the history of the Devizes "carrier" case, in which a woman who suffered from a severe attack of enteric fever in July, 1905, caused cases of the disease in September and December, 1905, in July, 1907, and in July, September, and December, 1908. The Winsley Sanatorium for pulmonary tuberculosis is largely supported by the town council of Bristol, which contributes £1400 annually for the maintenance of 20 beds, and which has a capital interest in the institution to the extent of £6000. The following figures show the after-history of the patients discharged from the sanatorium. Of 45 discharged in 1905 there were, on Dec. 31st, 1908, 21 dead and 5 whose whereabouts were unknown, while of 67 discharged in 1906, 29 were dead on that date.

City of Nottingham. - Dr. Philip Boobbyer, in presenting his twentieth annual report, estimates the population of the city at 260,449 for 1908, while the birth-rate per 1000 for the same year was 26.6, and the death-rate 15.2. The infantile mortality was 145 per 1000 births. He deplores the decline of vaccination in Nottingham, and he points out that the present vaccination law has swelled the ranks of abstainers from vaccination, and as this was not the end which it was intended to serve, it is difficult tojustify its continued existence. Diphtheria antitoxin is now not only given to the patients admitted to the isolation hospital, but it is distributed gratuitously to medical men in attendance upon poor patients on application. But, notwithstanding this liberal arrangement, a considerable number of patients are yearly brought to notice to whom, although the disease was early recognised, antitoxin has either not been administered, or, if administered, this has been done too late to obtain any real benefit. This is a very serious condition of affairs, and one which cannot be allowed to continue indefinitely. It will therefore be well for the medical practitioners who are thus tardy in administering antitoxin to consider their position. The death-rate from enteric fever in Nottingham is still unduly high, and Dr. Boobbyer ascribes its maintenance to the practically undiminished continuance of the conservancy system of excrement disposal, and in this connexion he makes an instructive comparison with certain other towns. He states that in the "seventies" the enteric fever death-rate in Nottingham was rather below the mean rate of the other large cities taken together-i.e., the Nottingham death-rate was then about 45 per 100,000, as compared with 48 per 100,000 in the other great towns. But although from the "seventies" onwards the enteric fever death-rates of the great towns had fallen to 20 per 100,000 at the end of the last century, the death-rate of Nottingham had only fallen to 29—i.e., the mortality was 45 per cent. more in Nottingham than in the large towns as a whole. During the decade ended 1907 the average enteric fever death-rate in Nottingham was 24 per 100,000, as compared with 10 in the great towns, and during 1908 the Nottingham death-rate (11 per 100,000) was still 36 per cent. above that in the great towns. Dr. Boobbyer then contrasts Nottingham with Leicester, where the water-earriage system has been substituted for the conservancy system, and he shows that pari passu with this conversion in Leicester the enteric fever death-rate has steadily declined as well as the death-rate from diarrhoea, and he contends that this decline cannot be due to reglulation of the shell-fish trade, since the supply of Nottingham and Leicester is identical. In passing, it is of interest to take note of the fact that in 1908 no less than 78 per cent. of the recognised cases of enteric fever were sent to hospital, and in connexion with the practice adopted at the Nottingham Isolation Hospital it may be pointed out that open-air treatment is still employed as far as possible for all cases of acute specific diseases. Dr. Boobbyer addsthat although this practice is undoubtedly advantageous in practically all such cases, its advantage is most apparent in a disease such as scarlet fever in which septic complications are liable to prevail; and as regards these cases the open corridors between the ward blocks are used in rough weather, but whenever weather permits the patients are nursed in the open, the beds being placed on the paths or grass immediately outside the ward blocks. But the labour involved in thus moving beds is considerable, and Dr. Boobbyer suggests that as the open-air treatment for the diseases dealt with in the isolation hospital has passed beyond the experimental stage it would be well if verandahs were built along one side of each ward block, such verandahs communicating with the interior of the wards by doors formed by prolonging the existing windows to the floor level.

City of Cork. - Mr. Denis D. Donovan tells us in his current annual report that at one time typhus fever was rife in Cork, there having in 1881 been 1406 cases with 88 deaths. In the decade 1879-1888 there were 4863 cases, in 1889-1898 547 cases, and in 1899 to 1908 122 cases. This gratifying decline the medical officer of health attributes in great measure to the provision by the corporation of about 550 working-class dwellings, as well as to the reduction of overcrowding, the removal of the families of the patients to the reception house, and the isolation of the patients themselves. It would be helpful if Mr. Donovan would in a subsequent report furnish the date of the first use of the subsequent report turns the date of the first use of the reception house and of the isolation hospital, as well as of the number of persons removed annually to each, as such a statement might be of considerable value. There were 88 cases of enteric fever with 16 deaths in Cork during 1908, and it does not seem at all clear as to what they were to be attributed. But in addition to these 88 cases of enteric fever there were, we discovered little later in the report as many as 55 cases. we discover a little later in the report, as many as 55 cases of "simple continued fever" which the medical officer of health regards as somewhat akin to typhus fever and as dependent upon the same conditions. The two conditions, typhus fever and continued fever, are, he adds, frequently met with in the same house. It is not clear from the report how far these cases of continued fever are isolated. The city of Cork has, the report states, the highest death-rate from pulmonary tuberculosis of any town in Great Britain and Ireland, the death-rate for 1908 being 3.22 per 1000. Cork still takes its water-supply from the river Lee, which is a polluted river, and although the degree of pollution has been reduced of late the medical officer of health is obviously far from satisfied with the filtration which the river water receives. As he rightly observes, a river supply such as that in question should be filtered by means of "properly constructed filter beds."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 7852 births and 3845 deaths were registered during the week ending Oct. 16th. The annual rate of mortality in these towns, which had been equal to 12.3, and 12.9 per 1000 in the two preceding weeks, declined again to 12.2 in the week under notice and was lower than in any week since the end of August; in London the rate last week did not exceed 12.0 per 1000. The lowest annual rates of mortality recorded in the 76 towns last week were $6\cdot0$ in Hornsey, $6\cdot7$ in Handsworth, 6.8 in Willesden, and 7.1 in Croydon; the rates in the other towns ranged upwards, to 17.5 in Liverpool, 17.8 in Grimsby, 18.6 in Merthyr Tydfil, and 18.9 in Oldham. The 3845 deaths in the 76 towns last week showed a decline of 221 from the number returned in the previous week, and included 387 which were referred to the principal epidemic diseases, against numbers declining steadily from 849 to 402 in the seven preceding weeks; of these 387 deaths, 208 resulted preceding weeks; of these 387 deaths, 208 resulted from diarrhosa, 51 from diphtheria, 40 from measles, 34 from scarlet fever, 27 from whooping-cough, and 27 from (principally enteric), but not one from small-pox. The 387 deaths from these epidemic diseases last week were equal to an annual rate of $1\cdot 2$ per 1000, against rates declining in the seven preceding weeks from $2\cdot 7$ to $1\cdot 3$. No death from any of these epidemic diseases was registered last week in Leyton, Norwich, Halifax, Hornsey, or in five other smaller towns; the annual death-rates therefrom

ranged upwards, however, to 4 · 3 in Grimsby, 4 · 6 in Rhondda, 5.9 in Great Yarmouth, and 6.1 in Hanley. The deaths attributed to diarrhosa in the 76 towns, which had declined in the seven preceding weeks from 676 to 230, further fell last week to 208, but caused annual death-rates ranging upwards in the several towns to 2.0 in Middlesbrough, 2.1 in Grimsby, 2.2 in South Shields, and 3.9 in Great Yarmouth. The fatal cases of diphtheria, which had been 43 and 28 in the two preceding weeks, rose last week to 51, and exceeded the number returned in any week since the middle of August; they included 14 in London and its suburban districts, 5 in Liverpool, 5 in Manchester and Salford, 4 in Hanley, and 3 in Hull. The deaths from measles, which had been 17 and 30 in the two previous weeks, further rose last week to 40, including 4 in Manweeks, further rose last week to 40, including 4 in Manchester and Salford, 4 in Rhondda, 4 in Newcastle-on-Tyne, and 3 in Bristol. The 34 deaths from scarlet fever were fewer by 6 than the number in the previous week; 13 occurred in London and West Ham, 5 in Liverpool, 4 in Manchester and Salford, and 3 in Birmingham and King's Norton. The 27 fatal cases of whooping-cough showed a marked decline, and were fewer than in any previous week of the year, but showed a proportional excess in Great Yarmouth. The deaths referred to "fever," which had been 17, 21, and 24 in the three preceding weeks, further rose last week to 27; they included 8 in London and West Ham, and 2 both in Portsmouth and in Grimsby. The number of scarlet fever patients under treatment in the Metropolitan Asylums and London Fever Hospitals, which had steadily increased in the seven preceding weeks from 2347 to 2745, had further risen to 2810 on Saturday last; 371 new cases of this disease were admitted to these hospitals during last week, against 438, 373, and 324 in the three preceding weeks. Two cases of small-pox were admitted to the Metropolitan Asylums of small-pox were admitted to the Metropolitan Asylums Hospitals during last week. Of the 1114 deaths registered in London last week, 167 were referred to pneumonia and other diseases of the respiratory system, against 132 and 186 in the two preceding weeks, and were 16 below the corrected average number in the corresponding week of the five years 1904-08. The causes of 27, or 0.7 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death registered during last week were duly certified in London, Bristol, West Ham, Sheffield, Newcastle-on-Tyne, Hull, Nottingham, Leicester, and in 52 other smaller towns; the 27 uncertified causes of death in the 76 towns last week included 6 in Birmingham, 3 in Liverpool and in Manchester, and 2 in St. Helens and in Gateshead.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 838 births and 456 deaths were registered during the week ending Oct. 16th. The annual rate of mortality in these towns, which had been equal to 13.8, 13.1, and 12.0 per 1000 in the three preceding weeks, rose again to 12.8 in the week under notice. During the 13 weeks of last quarter the annual death-rate in these Scotch towns averaged 12.8 per 1000, and exceeded by 0.7 the mean rate during the same period in the 76 large English towns. The annual death-rates last week in these Scotch towns ranged from 6.7 and 9.6 in Leith and Paisley to 13.7 in Glasgow and 15.6 in Perth. The 456 deaths from all causes in the eight towns last week showed an increase of 28 upon the number returned in the previous week, and included 45 which were referred to the principal epidemic diseases, corresponding with the number in the previous week. These 45 deaths were equal to an annual rate of 1.3 per 1000, and slightly exceeded the mean rate (1.2) from the same diseases last week in the 76 English towns. The 45 deaths from these diseases in the Scotch towns last week included 15 from diarrhosa, 12 from diphtheria, 8 from measles, 5 from scarlet fever, 4 from "fever," and 1 from whooping-cough, but not one from small-pox. The 15 deaths attributed to diarrhoea in the eight towns showed a further decline from the numbers returned in the two preceding weeks; 6 occurred in Glasgow, 3 in Dundee, and 2 both in Edinburgh and in Paisley. The 12 fatal cases of diphtheria corresponded with the number in the previous week, and included 8 in Glasgow (as in the previous week) and 2 in Edinburgh. The 8 deaths from measles, of which 7 were returned in Glasgow, showed a considerable increase

upon recent weekly numbers. The 5 fatal cases of scarlet fever included 3 in Glasgow, and all the 4 deaths referred to "fever" were returned in the same town; of the latter, 3 were certified as enteric and 1 as cerebro-spinal meningitis. The deaths referred to diseases of the respiratory system in the eight towns, which had been 66 and 59 in the two preceding weeks, further declined last week to 58, and corresponded with the number in the corresponding week of last year. The causes of 14, or 3.1 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 0.7 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of rather more than a million, 597 births and 334 deaths were registered during the week ending Oct. 16th. The annual rate of mortality in these towns, which had been equal to 16.9, 16.2, and 15.1 per 1000 in the three preceding weeks, rose slightly to 15.2 in the week under notice. During the 13 weeks of last quarter the annual death-rate in these Irish towns averaged 15.8 per 1000, whereas during the same period the mean death-rate did not exceed 11.9 in the 76 largest English towns and 12.6 in the eight principal Scotch towns. The annual death-rate during last week was equal to 16.0 in Dublin (against 17.5 and 16.8 in the two preceding weeks), 14.0 in Belfast, 21.2 in Cork, and 23.2 in Limerick; while the mean rate in the 16 smallest Irish towns did not exceed 12 3 per 1000. The 334 deaths from all causes in the 22 town districts last week showed an increase of but 4 upon the declining numbers in recent weeks, and included 29 which were referred to the principal epidemic diseases, 29 which were referred to the principal epidemic diseases, against 42 and 37 in the two preceding weeks; these 29 deaths were equal to an annual rate of 1.3 per 1000, corresponding with the rate from the same diseases last week in the Scotch towns, and slightly exceeding that in the 76 English towns. The 29 deaths from these epidemic diseases in the 22 Irish towns last included 10 from diseases. week included 14 from diarrhoa, 6 from "fever' (enteric), 6 from whooping-cough, 2 from diphtheria, and 1 from scarlet fever, but not one either from measles or small-pox. The 14 fatal cases of diarrhea showed a further decline of 8 from the numbers in recent weeks, and included 4 in Dublin, 5 in Belfast, and 4 in Cork. Of the 6 deaths from enteric fever, 3 occurred in Belfast, and 1 each in Dublin, Drogheda, and Newry. The 6 dai cases of whooping-cough included 3 in Limerick and 2 in Belfast. The 2 deaths from diphtheria occurred in Dublin and Lurgan. The 50 deaths referred to pneumonia and other diseases of the respiratory system last week in the 22 towns corresponded with the number in the previous week. The causes of 13, or 3.9 per cent., of the deaths in the 22 towns last week were not certified by a registered medical practitioner or by a coroner; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 0.7 per cent., but was equal to 3.1 per cent. in the eight Scotch towns.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

In accordance with the provisions of His Majesty's Order in Council of August 11th, 1903:-Surgeon Fernand Louis Joseph Marie de Verteuil has been allowed to withdraw from the Royal Navy with a gratuity.

The following appointments are notified: - Fleet-Surgeons: G. Ley to the *Niobe*, for voyage out, and to the *Kent*, on recommissioning; F. A. Brice to the *Ariadne*; W. Bett to the Swile, on recommissioning; and E. Sutton to the Niobe, for voyage home. Surgeons: J. Glaister to the Niobe, for voyage out, and to the Kent, on recommissioning; and C. J. O'Connell to the Sutlej, on recommissioning.

ROYAL ARMY MEDICAL CORPS.

Captain M. F. Foulds, from Chatham, has been appointed Specialist in Operative Surgery in the Belfast District, vice Captain G. J. S. Archer. Major F. W. Hardy, Sanitary Officer, Southern Command, has been transferred to the Eastern Command for duty, vice Captain R. T. Brown. Captain F. P. Lauder has been appointed to the medical

charge of the officers and their families, and the women and children, Marlborough Lines, Aldershot, vice Major J. Poe. Captain C. H. Straton has been appointed Specialist Sanitary Officer, Eastern Command, vice Lieutenant-Colonel J. V. Salvage.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Supplementary List: Lieutenant R. Magill is confirmed in that rank.

TERRITORIAL FORCE.

Royal Army Medical Corps.

1st Highland Field Ambulance: Lieutenant Peter Howie

to be Captain (dated Sept. 14th, 1909).
2nd Scottish General Hospital: Captain John Dixon Comrie, from 3rd Lowland Field Ambulance, Royal Army Medical Corps, to be Major (dated July 22nd, 1909). Attached to Units other than Medical Units.—Captain

William Roxburgh to be Major (dated Jan. 18th, 1909).

THE WEST AFRICAN MEDICAL STAFF.

In accordance with the recommendations of the recent Departmental Committee on the West African Medical Staff, the Secretary of State for the Colonies has appointed the following gentlemen to be an Advisory Committee on medical and sanitary questions connected with the British colonies and protectorates in Tropical Africa:-Mr. H. J. Read, of the Colonial Office (chairman); Sir Patrick Manson, senior lecturer, London School of Tropical Medicine; Sir Rubert Boyce, Dean of the Liverpool School of Tropical Medicine; Mr. C. Strachey, of the Colonial Office; Dr. W. T. Pront, late Principal Medical Officer, Sierra Leone; Dr. Theodore Thomson, of the Local Government Board; Dr. W. J. Simpson, Professor of Hygiene, King's College, London; and Dr. J. K. Fowler, late Dean of the Faculty of Medicine, University of London. Mr. A. Fiddian, of the Colonial Office, will act as secretary to the Committee.

Correspondence.

"Audi alteram partem."

THE TREATMENT OF ADDER BITES. To the Editor of THE LANCET.

SIR, -A note in THE LANCET of August 21st on this subject tempts me to send you a short account of a case which I recently attended. About 4.30 P.M. on Sept. 11th a boy, aged 14 years, was brought to my surgery by his mother, who said that he had been bitten on both hands by a viper which was produced for inspection. This must have happened as far as I can judge rather less than half an hour before I saw him. He was suffering from considerable shock, with faintness, pale moist skin, and a tendency to vomit. There were the marks of a bite on the ulnar side of the right little finger and of another on the dorsum of the first phalanx of the left middle finger. Both hands were greatly swollen, the cedema and ecchymosis extending well up into the forearms. The condition on the left side was decidedly the more severe, that hand having almost the appearance of a small boxing glove. Nothing in the way of first-aid treatment had been done. I at once applied a Bier's elastic bandage with moderate tightness to each arm at the elbow and made free incisions in the long axis of the fingers over the bites. Free hæmorrhage followed, after which gauze dressings were applied and the patient sent home to bed, where he vomited freely three or four times. I then applied hot fomentations of Gamgee tissue soaked in permanganate of potash solution, after having soaked the limbs in baths of the same solution for half an hour. No anti-venom serum being obtainable locally I wired to Burroughs and Wellcome and obtained it by 3 A.M. next morning, and injected 25 cubic centimetres into his flank. After doing so I removed the Bier's bandages; these had been in position from the first, about 11 hours in all, but I relaxed the tension in them somewhat on settling the boy in bed the previous evening, so that he might wear them without danger or too much discomfort until the anti-venom serum arrived. The hands and forearms were much swollen, the hands boggy, and the forearms brawny and very hard up to the lower edges of the bandages, and the skin was almost uniformly

discoloured by ecchymosis. The condition of the arms above the bandages was normal. When seen at 11 A.M. When seen at 11 A.M. the same morning the cedema of the hands was slightly less, but the brawny swelling had extended to the level of the axillary folds and the axillary glands were enlarged and extremely tender. There had been no more vomiting since the previous evening and the general condition was decidedly improved. At 5.30 P.M. he was much more comfortable, the cedema was about the same in extent but less tense, and he was taking light food well. Hot lysol fomentations were ordered for both hands. Next day his condition was good, the arms were less painful, and the swelling was perceptibly less. Antiphlogistine dressings were applied to both limbs at intervals for the next few days, the axillary glands gradually subsided, and by Sept. 21st the patient was getting about and enjoying the prospect of an extension of his schoolboy's holiday.

As to how far the injection of anti-venom serum was of use, I must leave to your readers. The serum which I used is stated to be an antidote to the poisons of cobra, daboia, rattlesnake, and krait; the poisons of the rattlesnake and the English adder are both classed as "viperine," that beside the chance of doing good by using a serum which may protect against the venoms of snakes in general I hoped that the antidote to the rattlesnake might also protect against our English adder. At the worst it did no harm.

It seems to me that in cases of snake-bite the use of Bier's elastic bandage is clearly indicated. It is of little use to incise the area of the bite if consequent hæmorrhage is prevented by a rigid ligature or tourniquet. Further, the latter can be applied only for a very limited time without injury to the limb, and on its removal there is nothing to impede absorption of the venom into the general system. the other hand, an elastic bandage can be so adjusted as to be applied for a period of many hours; the congestion produced by it encourages hemorrhage after incision; and when this has stopped, the extrusion of the venom into the bath or fomentation or dressing which is applied to the wound is facilitated by the vis a tergo of the arterial stream and by the obstruction to the venous and lymphatic return.

I am, Sir, yours faithfully, B. B. SAPWELL, M.B., B.C. Cantab.

Aylsham, Oct. 5th, 1909.

RECEIVING HOUSES FOR LUNATICS.

To the Editor of THE LANCET.

SIR,—The London County Council at its last meeting by a majority of one vote decided to apply for Parliamentary powers to establish one receiving house for lunatics, the original resolution being to provide for four such institutions. The existing practice is for all poor lunatics in the county of London to be taken to the infirmary or workhouse of the union to which they belong. In some districts the mental wards are situated in the workhouse, whilst in others they form part of the infirmary. Undoubtedly they should con-stitute a portion of the latter institution, which is devoted entirely to the treatment of the sick under the direct superintendence of a medical man, and except in very few instances this is the case, the exceptions being due to the fact that Poor-law affairs have for many years been in a very unsettled condition. Threats of transference of authority and of abolition have been made over and over again, and the feeling of uncertainty as to the future which these prognostications have caused has resulted in an unwillingness on the part of boards of guardians to spend any money on bricks and mortar with a possibility of the buildings being rendered unnecessary in a few years' time.

The line of practice adopted by the medical officers has been to send as few cases as possible away to the asylums. It has been found that a short detention will cure more than a half of the cases admitted. In 1902, 8076 cases of lunacy were admitted to metropolitan infirmaries and workhouses and 3920 were subsequently sent to lunatic asylums. In 1903, out of 8004 admissions, 3792 were sent away. In 1904 the figures were 7654 admissions and 3716 transfers. In 1905—and there is no later return—there were 7322 admissions and 3583 relegations to asylums. The more modern infirmaries are enabled to keep their cases longer because their fully equipped mental blocks give them more room. These naturally show a better rate of recovery. At Lewisham, for instance, which has a specially designed pavilion, our percentage of transfers to asylums has been for years about 33 per cent. The present system ensures that only confirmed cases are sent to asylums; it thus obviates the stigmatising as lunatics of from 50 to 66 per cent. of the patients, whose relatives are thus spared the pain caused by the infliction of an unnecessary blot upon the escutcheon of the family history. The infirmaries, being within reasonable distance of the friends, are easy of access for the purposes of visiting and for the necessary interviews with doctors and

Printed statements published by the asylums committee assert the necessity for the patients being placed under treatment as early as possible, implying that the County Council has something better to offer than the system which is in existence. So far as actual experience in the treatment of incipient lunacy is concerned, they can advance no claim for special knowledge, as for the past 15 years they have had no such cases sent them, all having been retained for the statutory period in the infirmaries and workhouses. The crowning act of audacity on the part of this committee has been to quote a paragraph from the recent report of the Royal Commission on the Care and Control of the Feeble-Minded, written in praise of the present system as practised in London, and by judicious omission and pruning to make it appear as though the words had reference to its suggested reception houses. The paragraph in point is No. 712. its desire for aggrandisement the asylums committee naturally has to make as good a case as possible, but this is scarcely playing the game. To my mind it is not desirable that the body responsible for the detention of lunatics should also be entrusted with their certification. Under the present system if a mistake should occur the asylum authorities would be quick enough to rectify it, but would there be an equal inducement for keenness if they were responsible for the initial stages?

I trust that Parliament will not allow the London County Council to force its hand. The whole of the Poor-law system is in the melting-pot, and it is quite possible that the County Council may not be the body chosen to remould it. Under any circumstances it should not be allowed to steal a march and to plunge the ratepayers into expense for a scheme which, after all, may not be even an intelligent anticipation.—I am, Sir, yours faithfully, F. S. Toogood, M.D. Lond.,

Medical Superintendent, Lewisham Infirmary; Lecturer upon Lunacy Law to the School of Sociology.

Lewisham, Oct. 18th, 1909.

THE BENHAM TOP.

To the Editor of THE LANCET.

SIR, -Dr. F. W. Edridge-Green's explanation in THE LANCET of Oct. 16th does not quite answer my question in the previous issue. As the black lines correspond to a portion of the retina which has not been stimulated, so also must the black half of the disc of which, as he says, they are a continuation. The question therefore remains why one should give an after-image of green and the other of red. It seems curious to speak of the "after-image" of an object that has not stimulated the retina at all, but apart from that difficulty the problem unsolved is, Why should the black mass produce an effect of green and its continuation one of red?

I am, Sir, yours faithfully, th, 1909. CHARLES E. BENHAM. Colchester, Oct. 18th, 1909.

IS SNOW-WATER UNWHOLESOME?

To the Editor of THE LANCET.

SIR,—A peculiar interest is attached to Dr. G. A. Atkinson's statement that he and "dozens of men" can drink large quantities of snow-water without harm, for not only does it enter into conflict with the admitted testimony of experienced guides but it would also appear to be a direct negation of well-established theoretical principles.

In looking into the question as to whether a particular water is fit to drink it is useless to rely upon an ordinary chemical analysis which merely expresses the percentage of salts, because it disregards the fundamental fact that in consequence of solution in water these salts break up into a larger number of molecules than is indicated by their chemical formulæ—i.e., undergo ionisation; and it is upon the number of ions per unit volume that the physiological action of water depends. Now, the presence of electrically charged ions in a solution is the cause of electrical conductivity in that solution. Without the liberation of ions no current passes, and the two phenomena-ionisation and electrolytic

conductivity—run on parallel lines. The conductivity of a solution is, in fact, proportional to the number of dissociated molecules of matter contained therein, so that the coefficient of electrical conductivity will give us an accurate record of the extent of ionisation. Ordinary drinking water has a fairly high coefficient of conductivity, and this implies that it must contain ions in more or less quantity. On the other hand, the purest natural water, obtained from natural ice or snow, has only a conductivity of 2.13, and this figure represents the relative number of ions present.

Now, what effect can this low ionisation have upon the harmlessness or otherwise of the water as a drink? According to the kinetic theory, the molecules of all substances above the temperature of absolute zero are in a state of incessant motion. When a solution is brought into contact with a semi-permeable membrane, such as is to be found in animal tissue, the water can freely percolate through, but the molecules of the dissolved substances find the barrier impermeable. Yet, though they cannot penetrate the septum, they can, and do, exert a continual pressure upon it by virtue of their perpetual movement; this osmotic pressure is regulated by the number of molecules held in solution, but is independent of their nature. Since an ion in solution ranks as a molecule, whether it represents an atom or a group of atoms, it follows that the osmotic pressure exerted by snow-water is extremely low. But the blood service has a very considerable osmotic pressure, due chiefly to its NaCl content, and this is maintained at a nearly constant level. When, then, two fluids of such different osmotic pressure are lying on either side of the stomach wall (which is permeable to water from blood to stomach, but not from stomach wall to blood) there must be a relative increase in the velocity of the osmotic stream from the blood, since there is only a diminutive counterstream opposed to it. The tendency would then be for the epithelial cells of the stomach wall to become swollen, and perhaps loosened, by the fluid that is drawn from the higher to the lower pressure level. In fact, the drinking of snow-water is apt to produce an urticaria of the stomach mucous membrane, with all its attendant symptoms of gastric distress: it acts as a protoplasmic poison on the gastric cells simply by virtue of its want of approximation to the normal osmotic relations of the body fluids. It is not the low temperature of the water (though that certainly assists by depressing the warning sense of taste) but its extreme purity that carries danger with it.

The same considerations, of course, apply to the not un-common experience of finding that, after a time, patients object to being given ice to suck, complaining that it nauseates them. Under such circumstances artificial ice is often much better tolerated than the natural product, not because it is purer but for the very opposite reason. Its coefficient of conductivity is as high as 137, and therefore it approaches more nearly in characteristics to ordinary tapwater. Since, then, both reason and practical experience seem to support your contention that "melted snow has a tendency to produce very harmful symptoms," I think we may legitimately indulge in a paradox, and assert that the toxicity of uncontaminated water is only commensurate with

its purity.

But when we come to question the relationship between snow-water and simple goitre we are on much more un-certain ground, and I would be inclined to reverse Dr. Guthrie's suggestion and say that the old doctrine that snowwater is generally unwholesome has led to the belief that it causes so terrible a condition as goitrous cretinism. Certain it is that when a disease is ascribed in one district (e.g., the Alpine) to the purity of the water, and in another (e.g., Staffordshire) to the Ca and Mg constituents of the water we are far from arriving at its true etiology. That the latter supposition is untenable seems clear when we remember the number of patients who drink the earthy alkaline and calcareous waters of such spas as Contrexéville or Wildungen. These resorts would soon lose their popularity if the unhappy visitor was to be penalised for the cure of his urinary disorders by the unwelcome acquisition of a bronchocele. And if snow-water is responsible for the condition the recommendation to distil the water of goitrous regions is at least a little curious.

The truth seems to be that any influence the condition of the water has on the endemic factor is only a slight one. Martin 1 has clearly shown this in an inquiry into the causes

of goitre as met with in Staffordshire, and McCarrison,2 in a very convincing paper, goes further and adduces strong arguments in favour of the disease being due to an intestinal parasite which has its external habitat in calcareous soil. He points out, too, that filtration of the water does not prevent or cure the disease as long as people live in the infected area, although an organically impure water may further its spread.—I am, Sir, yours faithfully,
Blackpool, Oct. 20th, 1909. RALPH S. OLDHAM, M.D. Dub.

THE ETIOLOGY OF LEPROSY. To the Editor of THE LANCET.

SIR,-With reference to your annotation in THE LANCET of Oct. 16th on "The Utility of the Examination of the Nose and Nasal Secretions for the Detection of Leprosy," the idea that leprosy started in the nose is an old one. In a general review of leprosy which I contributed to the Quarterly Review (No. 394, April) in 1903, I mentioned the view of Pliny on the point, viz.: "Diximus elephantiasim ante Pompei Magni estatem non accidisse in Italia, et ipsam a facie sæpius incipientem, in nare prima veluti lenticula, mox increscente per totum corpus, maculosa variis coloribus et inæquali cute, alibi crassa, alibi tenui, dura, alibi ceu scabie aspera, ad postremum vero nigrescente et ad ossa carnes adprimente, intumescentibus digitis in pedibus manibusque" (Pliny, Book XXVI., I., 5 (Ed. Teubner, Leipzig, 1897, p. 176). This opinion of Pliny is also referred to by Fracastor in his chapter on "De Elephantia" (Caput XIII., Liber ii., de Contagionibus, et contagiosis morbis, et eorum curatione).

A few years ago Sticker, a German observer, expressed the opinion that leprosy practically always began in the nose. This is too sweeping a statement. But the possibility of such a mode of infection should always be borne in mind, especially from the point of view of early treatment, which should be energetic. As to "acid-fast" bacilli generally, it has been shown that they may normally inhabit the nose,

quite apart from leprosy-a point to bear in mind.

I am, Sir, yours faithfully, GEORGE PERNET, M.D., Harley-street, W., Oct. 18th, 1909. English Editor of Lepra.

"SUITABLE FEES."

To the Editor of THE LANCET.

-At a meeting of the South-West London Medical Society held in Bolingbroke Hospital the enclosed correspondence was brought before the members, and they, feeling that it was a matter which should be brought before the profession at large, asked me to forward it you for early publication.

I am. Sir. vours faithfully

LEONARD S. MCMANUS.

President, South-West London Medical Society. Spencer-park, S.W.

[COPY.]

Metropolitan Borough of Wandsworth, Council House,
Wandsworth, S.W., 4th October, 1909.

Dear Sir.—A committee of this council have under consideration the
desirability of retaining the services of a medical practitioner in each of
the five districts into which the borough is divided to examine the
council's employees who claim sick allowances in cases of accident or
illness, and to certify whether or not they are capable of discharging
their duties. Before making a recommendation on the subject to the
council the committee are desirous of ascertaining the approximate cost
of the proposed scheme, and from inquiries which have been made the
following appear to be suitable fees for the work. (a) If the employee
attends at the medical practitioner's surgery 1s. per case for each
examination and report: (b) If the employee is unable to attend at the
surgery and the medical practitioner visits him at his home 2s. 6d. per
case for each examination and report.

Wherever possible the men would be required to attend at the
medical practitioner's surgery for the examination, but in some cases it
would be necessary for it to take place at the men's homes or elsewhere. With the view of assisting the committee in coming to a
decision on the subject I shall be obliged if you will inform me whether
you would be willing to undertake the work referred to in the district
No. 1 shown on the enclosed map on the terms above mentioned.
Kindly return the map when you reply.

I am, dear Sir. yours faithfully,

HEN. GEO. HILLS, Town Clerk.

Dr. B. Duke.

[DR. DUKE'S REPLY.] Windmill House, Clapham Common, Oct. 11th, 1909.

Windmill House, Clapnam Common, Cev. 1101, 1200.

DEAR SIR.—While thanking you for so kindly submitting to me the list of fees offered by the council for examining and certifying their employees I must respectfully decline such a tempting offer. I can only regret the council has such a contemptible opinion of the value of a medical man's time.

I am, dear Sir, yours faithfully,

B. Duee.

Henry Gee. Hills, Esq.

THE THIRD INTERNATIONAL CONGRESS OF THE MEDICAL PRESS.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

As I have briefly reported to your readers, the Third International Congress of the Medical Press was held in Budapest on August 27th of this year, just before the meetings of the International Medical Congress. The importance of the occasion will justify me in now giving a full account. The Congress was held in the Academy, a palatial edifice of Renaissance style built some 40 years ago in the most beautiful part of Pest, overlooking the Danube, close to the great suspension bridge and with the old and picturesque town of Buda just opposite. It contains a large library, a lofty reception-room, a historical picture gallery, and many commodious rooms for the meetings of learned societies. One of the largest of these rooms was placed at the disposal of the International Association of the Medical Press for its Congress and other meetings.

The Formalities of the Congress.

On Friday, August 27th, there was held the International Congress proper, at which any medical journal could be represented. On Saturday morning the General Assembly of the International Association of the Medical Press held its meeting, while the first part of Saturday afternoon was given up to a meeting of the international committee of that association. Thus on the Saturday only representatives of journals that are affiliated to the Association of the International Medical Press had a right to be present.

Early in the morning of Friday a large number of Press representatives were already assembled, when in the absence through illness of Professor Posner of Berlin, President of the Association, Dr. L. DÉJACE, editor of the Scalpel (Belgium), as Vice-President of the Association, took the chair. Professor M. DE LENHOSSÉK rose first on behalf of the Hungarian Association of the Medical Press to wish a hearty welcome to the members of the Congress. He expressed the desire felt by all his colleagues that the aspirations which had brought the congress together might be fully realised. In Hungary the medical press was young but progressive. The first Hungarian medical journal was issued in 1831 and it was not till 1857 that a second paper made its appearance. That second paper, after weathering many a storm, still exists and several other papers have sprung up since. If we include journals devoted to hygiene there are some 30 medical papers in Hungary. Better still, they were now united together in a press association and modestly claimed to take their stand by the side of the greatest publications of the world as fellow members of greatest publications of the world as fellow memoers of the International Association of the Medical Press. The Hungarian papers strove to make known the latest pro-gress achieved. They were at one with the moral principles proclaimed by the International Association of the Medical Press and would willingly participate in any endeavour to preserve the tone of the medical press as a whole. "The Hungarians are grateful to the association for having included their papers among those which have this aim," said Professor M. de Lenhossék, who concluded by again cordially welcoming the Congress to Budapest. After a courteous letter from Count Albert Apponyi, Minister of Public Worship and of Public Education, had been read, in which that energetic Minister regretted that he could not be present in person to welcome the Congress and this in the name of the Hungarian Government.

Professor Dr. CALMAN MULLER, President of the Sixteenth International Congress of Medicine, rose and said that he was pleased to have an opportunity of expressing his thanks to the medical press. But for the support of the press the International Medical Congress could never have attained its present magnificent developments. The press did not only record what occurred, but it prepared the road for the future. The true journalist was the precursor of his time. He was not content to relate what had happened but must go forward, hold up the light, and prepare the way for what was going to happen.

As acting President of the Congress Dr. L. DÉJACE responded to these welcomes in the name of the meeting,

had lent every assistance to assure the success of the present gathering. He then went on to point out that the medical press had become the instructor of the medical profession and was inspiring the medical practitioner with the desire to continue to learn after the obligatory portion of his education was terminated. Medicine could not stand still, while changes came not only from within but from without. New laws were made by countries to meet new necessities, which in their turn altered the position of medical practitioners. "We are now," said Professor Déjace, "as a profession beginning to treat society as a whole, where formerly we only treated its individual members. In such collective treatment governments and municipalities have to take part, and here comes in the most useful function of the medical press. It is for the medical journals to teach how we can best prepare for collective defence against the spread of disease. Fatal thrombus will result if the circulation of ideas is not well maintained."

Dr. R. BLONDEL, General Secretary of the Association, spoke next, and said that the meeting being open to representatives of all medical papers the agenda would treat questions of general interest where it was needed to find effective remedies for acknowledged evils. "The journals which are already grouped together," he said, "will resent any interference, but must make some sacrifice for the sake of union. On the other hand, we have to exclude those whose purport is to promote some trade or business interest. We must not let the commercial element trespass on the scientific and literary sides of our work, otherwise the medical press will sink to the level of the political press or fall into the hands of mere financiers. In this great struggle we must be unanimous and not fear if an individual paper here and there drops out of our ranks. We must remember that we are the servants of truth; that truth cannot be served unless we are free; that we must have strength to defend our freedom, and to secure that strength we must be united."

The History and Object of the Movement.

Dr. DÉJACE then vacated temporarily the chair so that he might present his report on the History and Object of the Association. He recalled how unmanageable the medical congresses had become and that, so far back as the congress held at Rome in 1894, Professor Posner of Berlin, Dr. Baudouin of Paris, and others had discussed the difficulties facing the medical press when it attempted to describe such vast and disorderly assemblies. In 1897 members of the French medical press, having debated these matters, decided to hold an international congress of the medical press in Paris during the Universal Exhibition of 1900. This congress took place on July 26th of that year, immediately after the Congress of Medical Deontology (medical ethics and economics) and just before the Thirteenth International Congress of Medicine. All who were present, he said, would remember the interest manifested on that occasion. for honorary president Professor Virchow and for acting president Professor Cornil, and we appointed a committee to decide whether it was advisable to form an international association of the medical press and to prepare for a second meeting. We met again at Brussels in 1901 and at Monaco in 1902, when, thanks to the gracious hospitality of Prince Albert of Monaco, the representatives of various nationalities were entertained for three days and drew up the rules and constitution of the association. In 1903, when the Fourteenth International Congress of Medicine met at Madrid, a Second International Congress of the Medical Press was held which definitely accepted the rules prepared at Monaco and thus the international association was definitely constituted. Since then the international committee of the association has met every year, while a general assembly was held at Lisbon in 1906, as now at Budapest, just before the International Medical Congress. Dr. Déjace then passed in review the various topics discussed at the annual committee meetings and larger triennial gatherings. The most diffi-cult question was to draw the line between legitimate and illegitimate publicity. Some thought that the ideal medical journal would be without any advertisements, but he admitted that as the medical press appealed to only one class of the public it might not be able to live on its circulation alone, while the advertisements were most useful to the profession by keeping before them a record of the resources that were at their disposal. But saying that he understood that the Hungarian Government the association would not recognise concealed advertisements

and refused to admit to affiliation journals that were distributed gratuitously. The Association of the Medical Press had endeavoured to prevent the publication of articles in the lay press that professed to be signed by medical men but which were not written by medical men, and in other ways had attempted to protect the public against paid "puffs," and he was sure that as time went on the efforts of the International Association of the Medical Press would be gratefully acknowledged by the public.

Dr. BLONDEL said that the paper just read did not need discussion, and he only rose to add some information to that already given. Two new associations had joined, the Polish Association and the Hungarian Association. On the other hand, the Portuguese Association had fallen out of the ranks, and the Americans, in spite of continued negotiations, had not yet come in. But if the United States of America could not as yet participate in our work we were actively supported from other parts of the New World, and he was glad to welcome, in the present assembly, representatives of the Brazilian and of the Mexican medical press. Russia was now coming back to the fold. It is true that this was unofficial, for anything like an international association was not tolerated in Russia. But the medical press in Russia had a very strong national organisation which was animated with the most friendly feelings towards the national associations of the medical press in all other countries.

The British Report and Proposals.

The PRESIDENT now called for the report of the British delegation. This had been translated and printed in French and was in the hands of all present, and was as follows:-

DRAFT REPORT FOR THE MEETING OF THE INTERNATIONAL

DRAFT REPORT FOR THE MEFTING OF THE INTERNATIONAL ASSOCIATION OF THE MEDICAL PRESS.

At the meeting of the International Committee of the Medical Press held in London in 1907 three resolutions dealing (1) with articles written by medical men in favour of medicinal products; (2) with medical advertisements generally; and (3) with the assigning of rights of republication of articles in medical journals to commercial firms by medical authors were agreed to. Inasmuch as the practical value of these resolutions must depend on the recognition of the principles involved by the general body of the medical profession in each country, they were submitted to the British Medical Association and were approved by it at its annual meeting last year (1908). As, however, the third resolution contained no provision with regard to the reproduction of articles by the medical authors themselves for the purposes of advertising medicinal products the following additional resolution was adopted at the annual meeting of the British Medical Association at Beliast in July this year (1909):—

of articles by the medical authors themselves for the purposes of advertising medicinal products the following additional resolution was adopted at the annual meeting of the British Medical Association at Beliast in July this year (1909):—

That it is the professional duty of medical authors of articles in medical journals to cooperate with the proprietors and editors of those journals in preventing any improper use of such articles for the purposes of advertisement.

This extension of the original resolution of the International Association of the Medical Press to provide that articles dealing with medicinal products written by medical men and published in medical journals shall not be reproduced by the manufacturers or by the authors for the purposes of advertisement without the specific consent of the editors, proprietors, or publishers, offers a safeguard against puffing. If manufacturers alone were required to obtain permission from the editors or publishers before reproducing articles dealing with drugs, preparations, or other chemical products, it might be possible that manufacturers might attempt to induce medical authors to undertake the reproduction of the articles for them, so that the provision contained in Resolution 3 would become nugatory. To prevent such evasion of the principle involved in Resolution 3 by a legal agreement between the author and the editor or publishers of the medical journal in which the article appeared would under English law at least be costly and troublesome, and such a legal document would be wholly unnecessary in the case of the majority of articles on therapeutics or pharmacology which are written in a disinterested manner by men who would not lend themselves to a dishonourable agreement. Since it appears that it would be difficult and inadvisable to deal with the matter by a legal document, it was recognised that a sufficient safeguard would be obtained if the medical profession declared that the republication of articles referred to without the consent of editors or p

What is Advertisement?

The British report gave rise to a great deal of discussion. Dr. NEUSTATTER, for Germany, agreed in principle with the British report, and then described his German experiences. The great difficulty was the limitations of the copyright law. Even when authors and their publishers were agreed, a business firm could reproduce for advertisement purposes what had been said and there was no redress, and he proceeded to mention several such cases.

Mr. W. H. ARMIT, for the British contingent, answered that the point at issue was not properly understood. There was a tendency to mix up the question of articles written expressly to serve for advertisement purposes and those referred to in the British report, which were written in good faith and were not meant to be used as advertisements, but which were so utilised by commercial houses in spite of the protests of the authors and the publishers. What the British section desired was to appeal to the entire medical profession to deal with the matter as a question of honour.

Dr. NEUSTATTER again rose, saying that the illegitimate use of such articles could not be prevented. Even if no one consented to their reproduction they would be reproduced all the same.

Dr. BLONDEL appealed to the Congress to keep to the question of improper advertisement or "réclames."

Dr. GRUN (Vienna) endeavoured to define what was meant by the word réclame. The grievance had reached such a point that the medical press tended to suppress therapeutic investigations. Men of science were afraid to test the action of a drug for fear of being accused of "puffing" some com-mercial product. He thought the International Association of the Medical Press should define what was justifiable and what was not.

Dr. R. JAFFÉ (Hamburg) agreed with Dr. Grün, and Mr. ARMIT informed Dr. Jaffé that advertisements offered to the English medical journals, THE LANCET and the British Medical Journal, were controlled by the editors.

Dr. FOVEAU DE COURMELLES (Paris) pointed out that customs differed in the different countries. In England there were very few medical journals and they were strong enough to do as they liked. It was difficult to define where legitimate publicity ended and "puffery" commenced. It seemed to him that the only positive distinction was the question of payment. If the parties interested paid to have the article written and published, then it was a "puff" or réclame. If they did not pay, then, however favourable the article might be, it was to be accepted as legitimate praise. But no one had the right to reproduce such an article for advertisement purposes. There were such things as copyright

Dr. Lucas-Championnière (France) remarked that there were in Germany poor persons who, under a scientific guise, made it a business to write "puffs." In France there were pseudo-medical journals, owned and published by druggists, which were "puffs" from beginning to end. What was needed was a scheme of measures to meet the different practices of the various nations. In France the copyright law could be used in certain circumstances, but not so in others, especially in regard to names. Thus the speaker had once written a paper on the benefits derived from the use of oxygenated water in medicine. Thereupon a manufacturer of absinthe introduced some oxygen in his absinthe and then quoted what the speaker had said on the benefits of oxygen and made it appear as if his absinthe was approved by the Dr. Lucas-Championnière wanted to prosecute speaker. the absinthe manufacturer, but his lawyer strongly advised him not to embark on so expensive and hazardous a course. "We must more clearly define what we mean and what is our position," said Dr. Lucas-Championnière, "but even then we should not be able to prevent our names from being used in vain."

Professor Ascoli (Italy) remarked that much depended on the ability of the editors to discriminate between legitimate and illegitimate publicity.

Mr. ADOLPHE SMITH (London) agreed that a clear definition of the terms used was needed. Dr. Blondel had said that a réclame was "a paid article." Surely this was only half the sentence. A réclame was an article paid for by a commercial firm to promote the sale of its products. journalist living as a journalist must be paid for the work he is commissioned or engaged to do. He could not live on thin air. The scientific journalist's position should be sufficiently independent to allow him to devote himself exclusively to the pursuit of truth.

Dr. FOVEAU DE COURMELLES doubted if there were any medical journalists, medical men who lived exclusively by journalism, in France, a view with which Dr. Lucas-CHAMPIONNIÈRE was not wholly in accord.

Dr. BLONDEL, in reply to Mr. Adolphe Smith, said that payment in return for the writing of puffs was illegitimate; he did not refer to legitimate payment for the writing of articles by professional journalists. "A réclame," he said, "is an article for which the writer is paid either by a commercial firm or by the owners of a paper and in which the writer has to express a favourable opinion concerning a drug, an appliance, or perhaps a method of treatment. The writer is not free to say what he conceives to be the truth: he turns out a venal article. We of this association are opposed to such articles because they obscure the truth and demoralise letters." This sort of article, he went on to say, had become a form for obtaining publicity; it was driving out the old and legitimate form of advertisement where the reader knew what was editorial and what was not. Many medical journals had a column which was usually denominated "Therapeutic Notes," and in France it was open to abuse. A certain sort of advertiser will, for instance, sign a contract for three years. At the end of the second year he will write a letter pointing out that he is a good advertiser and asking that a very serious and scientific note, which he encloses, may be published in the body of The very serious and scientific note proves to the journal. be a puff, but if it is not inserted the probabilities are that at the expiration of the three years the advertisement will not be renewed. Dr. Blondel insisted that it was necessary for medical journals to unite so as to stop this sort of thing, or in a few years the medical press of France and some other countries will be quite helpless. In Germany certain manufacturers have helped the medical press to get rid of a class of writers who offer to turn out "puffs." A list of those who approach commercial firms with such offers has been drawn up and communicated both to editors and manufacturers, with the result that this abuse is in a fair way to total extinction in Germany. Dr. Blondel thought that it might be a resolution of the Third International Congress of the Medical Press that all journals in the association should declare to their advertisers that the sale of space implied no other obligation on the vendors, and that such papers as would not assent to the proposal might be excluded from the association.

At this stage the discussion was brought to a close, and the Congress adjourned for lunch.

A Permanent Commission for the Organisation of International Congresses of Medicine and of the Allied Sciences.

At the afternoon sitting of the Congress the report submitted by Dr. DAWSON WILLIAMS concerning the formation of a Permanent Commission for the organisation of International Congresses of Medicine and of the Allied Sciences was discussed. This report having been translated into French was printed and distributed among the members present. Mr. ADOLPHE SMITH explained that the report had been fully discussed by the British Section of the International Association of the Medical Press, Dr. Squire Sprigge presiding. Several points had been altered and modified, and it might now be taken as representing the opinions of the British It might also be considered, if not as an amendment, then as an attempt to elaborate certain proposals that had been issued from Budapest and forwarded to the various national committees of the International Medical Congress. These latter proposals gave but few details and did not touch at all on the question of ways and means, but while providing for the constitution of a Permanent Commission also proposed to exercise discretion over the sectional resolutions and select those to be submitted to the plenary sessions. The British project in a preamble set forth the necessity of continuity and proposed the creation of a Permanent Commission consisting of delegates of national committees, secretaries of the sections of the previous congress, the president and general secretary of the forthcoming congress and of the congress just over. This would mean a sort of international parliament of about 70 members, quite a small congress in itself. Consequently it could not meet often but should meet immediately after each international congress and could be convoked between the congresses if some exceptional difficulty arose. The most important function of this Commission would be the election of a small executive committee called the bureau, consisting of not more than 20 members, which would meet at least once a year, and really do the work. So that this work should be continuous the bureau would appoint a permanent paid general secretary, possessing knowledge of three European languages, experience of congress management, and ready to take up his residence in the city where the next congress was to meet at least four months in advance.

Dr. Blondel opened the discussion by saying that at Budapest he had found the preliminary organisation very complete and systematic. The International Commission would meet in a few days and the representatives of all the nations would then discuss a proposal for the creation of a permanent commission consisting of only one member per nationality, and no representative whatsoever of the Press. It was the same idea as that put forward by the British Section, but with fewer persons, for the British proposed two representatives per nation and three representatives of the International Association of the Medical Press.

Mr. H. W. Armit said the object was to send the British proposal to the international meeting when it was held, in the hope that some at least of the suggestions it contained would be adopted.

Dr. DÉJACE, who was presiding, gave further explanations,

Mr. ADOLPHE SMITH pointed out that the British proposal differed in two important respects from the proposals emanating from Budapest. The first article of the Budapest scheme said in its first clause that the Permanent Commission would have "to examine resolutions adopted by the sections and select those which shall be submitted to the Plenary Assembly." This was so delicate a matter, bordering on the establishment of a censorship, that the British section had left it out altogether, thinking the whole subject needed very careful study before attempting to legislate upon it. Then also the draft regulations from Budapest said nothing whatsoever about the other congresses. Yet one of the very first objects in creating a permanent commission was to prevent clashing with other congresses. It was not generally realised how many members of the medical congress were also members of these other congresses. There was, for instance, deontology; this was not exclusively medical, but the ethics, the dignity and economics of the profession interested every medical man without exception. Only one international deontological congress as yet had been held, but it was to be hoped others would follow. Then the congresses, such as those on tuberculosis, hygiene, demography, alcoholism, food adulteration, housing of the poor, school hygiene, and the long list of special diseases, otology, dermatology, &c., all these had their periodical international meetings, and yearly the confusion was becoming worse confounded. What was needed was some permanent and international authority that would marshal all these various efforts, systematise them and establish order.

Dr. DÉJACE agreed that an authority capable of acting as a uniting link was very desirable, but he did not think the meeting could ask the International Medical Congress to form such a link.

Dr. Lucas-Championnière argued that as the International Medical Congress could not do it the medical press should undertake the task. "We," he said, "are separated, but our mission is to gather together and to unite dis-associated interests." He would support the arguments brought forward by Mr. Adolphe Smith. The press would be crippled if, for want of international organisation, two important congresses met at the same time. It was difficult enough to describe and to report one congress, let alone two. The organisations of medical and allied congresses should consult the international committee of the International Association of the Medical Press. The members of the committee had to attend these various congresses and knew all about them and were therefore the natural arbitrators in such matters. The press had to serve all the congresses, and the congresses dealing with sociology interested medical men nearly as much as those only concerned with purely and solely scientific subjects.

Mr. ARMIT said that the British section did not show the audacity of Dr. Lucas-Championnière and feared that as an organisation the medical press were not yet strong enough to carry out so ambitious a programme.

Dr. BLONDEL remarked that the International Congress on Tuberculosis, as also that on hygiene, had already permanent international commissions; what was needed was a link between these commissions.

Dr. LUCAS-CHAMPIONNIERE, speaking again, urged that the permanent commission of the International Medical Congresses should negotiate with the international committee of the International Association of the Medical Press as to when the medical congresses should meet, and considered that the latter body should be asked to advise in regard to the organisation of such congresses. As an international

association the debates of the journalists demonstrated that they were not always agreed in matters of ethics; but in respect to the organisation of medical congresses they were quite unanimous and possessed the necessary experience.

Dr. K. Jaffé agreed in principle but doubted whether the

other bodies concerned would also agree.

Dr. DÉJACE then consulted the meeting as to whether it would support the formation of a permanent commission for the international congresses of medicine, and this was

unanimously approved.

Dr. LUCAS-CHAMPIONNIÈRE said that all parties or congresses were free to found any organisations they might fancy. The point was that where such organisations or permanent commissions were formed, they would, one and all, have to avail themselves of the services of the medical press. A medical congress would do as it pleased; but the press would act for all, and should become, by its widespread experience, the natural international adviser.

Dr. BLONDEL said that the International Medical Congress had the same idea, but, nevertheless, no member of the press congress had been invited to take part in the meeting that was to decide as to the formation of a permanent commission. It so happened that two or three members of the Press Congress, being also secretaries of their national committees, were entitled to participate at the meeting in question. This was his own case, and Dr. Blondel offered to submit any proposal the Press Congress might make.

Dr. LUCAS-CHAMPIONNIÈRE said that some confusion had arisen. The question was whether the organisation formed by the medical press could become the permanent connecting link between the various congresses. At present the press had no voice at the meeting to be held by the International Commission of the present Medical Congress. "We can act "We can act for ourselves," he said, "and call upon other bodies to

support us."

Mr. ADOLPHE SMITH thought that a permanent international commission would need paid assistants to do clerical and other work, and also men of great diplomatic skill to manage. The press organisation did not as yet possess the men or the money to undertake successfully such a task; but it wanted to be represented in an influential manner on the permanent commission which the Medical Congress was about to appoint. Further he urged that the permanent commission of the International Medical Congress should federate with the permanent commissions of the other international congresses representing the allied sciences.

Dr. LUCAS-CHAMPIONNIÈRE expressed his satisfaction that the position was now clearly defined. The press must be largely represented in the work of the organisation of congresses, otherwise grave defects are sure to arise. "We therefore claim a big place where at present we have no place

Dr. JAFFE now formally proposed that the British report on the formation of a permanent commission for the organisation of International Congresses of Medicine and of the Allied Sciences be presented to the Commission of the present Medical Congress, so that this document, together with the observations made during the course of this debate by Mr. Armit and Mr. Adolphe Smith, might serve as a basis of discussion.

After a few more observations and explanations this proposal was formally put to the Congress and carried unanimously. The discussion on this subject was thus terminated.

What the commission of the Medical Congress did with the proposal presented to it by the Congress of the Medical Press and how it dealt with the entire question is recorded in THE LANCET of Sept. 11th (p. 800, et eq.), the result of the deliberations being that the President of the International Association of the Medical Press was included in the Permanent Commission.

Summaries and Translations of Original Articles.

The next subject for discussion was a report presented by Dr. BLONDEL on the advisability of printing summaries of original articles in various languages. Some Swedish and Norwegian medical journals already do this, he said, and it greatly facilitates the spread of knowledge.

Dr. M. DE LENHOSSÉK, President of the Hungarian Section of the International Association of the Medical Press, explained that Hungarian papers were also in the habit of publishing summaries of their contents in French

Professor DURUY thought this was an excellent practice,

as in the course of time men would find that their only chance of success depended on their ability to write in at least one of the three international languages.

Dr. NEUSTATTER said the most essential was to have a French summary of the English and German articles. Every German was obliged to learn French, and not 5 per cent. of

them knew English.

Mr. ADOLPHE SMITH said they had not the power to force the owners of journals to incur the expense of these translations; and the British representatives at the Congress had been instructed not to promise what they were not sure of being able to carry out.

The Italian delegates, Dr. CECHERELLI and Professor ASCOLI, suggested that Italian should be one of the international languages, but a proposal that summaries should be

in all four languages was rejected.

Finally, a resolution was carried recommending all journals affiliated to the International Association of the Medical Press to place at the conclusion of original articles a summary of the article "in one of the languages habitually employed for international relations."

Meeting of the General Assembly of the International Association of the Medical Press.

On the following day, Saturday, August 28th, was held the general assembly of the International Association of the Medical Press. The difference between this meeting and the Congress was that, instead of being open to all comers, only representatives of journals affiliated to the International Association of the Medical Press were admitted. Nevertheless, there were present delegates of the medical press assotions of Austria, Belgium, Brazil, Canada, Egypt, France, Germany, Great Britain, Hungary, Italy, Poland, Spain, and a Russian doctor, who, however, had to explain that, while sympathising in every way, it was illegal for Russians to belong to an international organisation.

At the commencement of the morning sitting Dr. LE CAVALIER of Montreal informed the meeting that in Canada there were three medical journals published in French and three in English. They desired to enter into regular com-munication with the medical press of Europe, so that the efforts made in Canada should not be ignored by the rest of

the world.

Dr. QUEVADO of Brazil found that in Brazil there was no one journal sufficiently distinguished to be unanimously chosen as leader; therefore, they were divided by jealousies. Consequently, he thought that great good might be achieved if some central body, acting from without, could call upon the various Brazilian journals and journalists to join the Brazilian Association of the Medical Press.

Dr. JAFFÉ explained how the black list of the authors of puffs had worked satisfactorily in Germany and urged that the editorial staffs of newspapers should control the adver-

tisement columns.

Mr. Armit again explained that the two leading medical journals in England-THE LANCET and the British Medical Journal—controlled their advertisements editorially. He stated that the British Medical Association and the British Section of the International Association of the Medical Press were both now investigating what sort of fees might be legiti-mately given to medical men who undertook to write impartial reports on clinical and pharmacological subjects. This question was very complex and much study was needed before practical proposals could be made.

Favourable reports were received as to the organisation of

the sections in Belgium, France, and Spain.

Dr. LUCAS-CHAMPIONNIÈRE suggested that to establish a system of insurance, or indeed any scheme of social work, might be of great service in strengthening the bond of union.

Dr. R. BLONDEL said that already proposals had been brought forward to, for instance, centralise all the subscriptions raised from time to time in various journals (1) to relieve distress; and (2) to erect monuments to deceased famous men. Passing to the general business, he said that though there were no representatives from Holland on the present occasion they had received a written report from Holland describing the efforts made to keep quack advertisements out of the Dutch papers.

Professor Andrea Cecherelli explained that the long faction fights in Italy were coming to an end, and that before the conclusion of the current year the medical press of Italy would be united in one single organisation, and able to take

its due share in the international movement.

Dr. CORMANOS PACHA said that that the Association of the Egyptian Medical Press was the youngest branch of the International Association, but it was none the less vigorous and anxious to play its part in the general movement.

Dr. BLONDEL announced that *l'Annuaire* of the asso-

ciation would appear as soon as the Italians had settled their differences.

The question of publishing summaries of original articles in various languages was again discussed, and Dr. Otto NEUSTATTER of the Dresden Gesundheitschrer urged that we were not called upon to select an official language, though he thought that, practically speaking, the French language would be generally employed. The point was to render the practice of translations more popular.

Professor Dr. Julius Donath (Budapest) explained that his paper, the Internetesseler Zeitschrift Epilepsia, was now published in three languages and they hoped shortly to add a fourth, the Italian language. Professor RECASENS of Madrid said a few words for Spanish, which was the language of South and Central America. After this the assembly adjourned for lunch, having contented itself with a general recommendation that translations should be made as often as possible.

Meeting of the International Committee of the Association.

During the midday interval the International Committee of the International Association of the Medical Press held The balance-sheet presented by the its annual meeting. treasurer was submitted and adopted. From this statement it appears that Norway heads the list for regularity of payments. The next point was the election of the officers or bureau of the association, it being understood that they would remain in office for four years if the next medical congress did not meet sooner. Professor Lucas-Championnière (France) was elected President, and Dr. Déjace (Belgium) and Professor Dr. M. de Lenhossék (Hungary) Vice-Presidents. Dr. Raoul Blondel as general secretary and Dr. Dawson Williams as treasurer were re-elected by acclamation. The committee, it was decided, would meet next year at Brussels, probably at the same time as the International Conference on Tuberculosis.

In the afternoon, when the general assembly of the International Association met again, it was decided that the ensuing International Congresses of the Medical Press should be held at the same time as the great International Medical Congresses. Therefore the next International Congress of the Medical Press will meet in England in 1913.

The Question of Puffery.

The assembly then proceeded to discuss once more the question of "puffs," still further insisting on the need of a definition, and it was proposed that the International Committee should prepare a report on the subject to be submitted to the next general assembly.

Dr. LUCAS-CHAMPIONNIÈRE was anxious to applaud the

stand made by the British medical journalists on the subject.

Dr. BLONDEL pointed out that the British proposal was to struggle against both forms of "puffs," the article written as a "puff" and the legitimate article which was subsequently and illegitimately used for purposes of advertisement. There were laws to protect copyright and these should be invoked.

A motion was then carried to the effect that in each country every effort should be made to apply such copyright laws as bore on the question.

The assembly, which had been well attended throughout, had now exhausted its programme, and after a few words of congratulations from the chair the members took cordial leave of each other.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

University of Bristol.

THE number of students entering the Bristol Medical School this first University session is 20, a definite increase on past years. There were 13 competitors for the entrance scholarship, the largest previous number having been 4. The returns for the faculties of science and engineering are also gratifying, the department of chemistry having received over 100 new students.

The Bristol Medico-Chirurgical Society.

The annual meeting of this society was held on Oct. 13th in the Medical Library of the University. The retiring President, Dr. J. Michell Clarke, having introduced his successor, Mr. James Swain, to the chair, the latter delivered his inaugural address. This was a most interesting résumé of the evolution of the art of surgery traced from the earliest times down to the end of the sixteenth century. It was illustrated by a series of lantern slides, judiciously chosen and excellently produced, representing surgical operations and instruments of all periods, beginning with an ancient Egyptian illustration of the operation of circumcision. The fact which Mr. Swain particularly emphasised was that in many respects there was little difference between the principles of surgery as practised by Hippocrates from those on which the operative procedures of the present day are based, a reflection which should engender humility in twentieth century surgeons. The report of the honorary secretary, Dr. J. A. Nixon, showed that the society is full of vigour. During the past year 30 new members is full of vigour. During the past year 30 new members had joined, while 22 had left the society, the total membership on Oct. 1st, 1909, being 166. The average attendance last year at the meetings (which are held monthly from October to May) was 41. The financial statement was also satisfactory, showing a balance in hand of £81 14s. 8d. The honorary librarian's report showed that the new borrowing scheme, initiated during the year 1908-09, had met with favour, 90 members having availed themselves of the opportunity of borrowing books. The library, which consists of books belonging to the society, to the medical faculty of the University, and to the two large hospitals, now contains 21,235 volumes and takes in 251 periodicals. By means of an arrangement with a metropolitan lending library the privileges of members are further extended.

The South-Western Poor-law Conference.

The annual Poor-law Conference for the South-Western district was held at Salisbury on Oct. 12th, under the presidency of Sir T. D. Acland. Mr. F. W. Oripps (vice-chairman of the Cirencester union) read a paper on the Proposed Abolition of the Workhouse. He urged that that institution need not be abolished, but that guardians should be relieved of the care of two classes, the epileptics and feeble-minded, who should be cared for under a similar system to the lunatic asylums, and that vagrants should be treated upon the lines of the recommendation of the vagrancy committee. Dr. Arthur H. Downes (senior medical inspector of the Local Government Board for Poor-law purposes), who was the invited speaker present, expressed his hearty agreement with the general principles of Mr. Cripps's paper. After a considerable discussion a resolution was unanimously passed expressing agreement with the scheme advocated by Mr. Cripps.

A Russian Tribute to Jenner.

On Oct. 4th, at Berkeley, Gloucestershire, Dr. Simon Shiwopiszew, director of the Russian Lymph Institution at Orel, and lecturer on vaccination, in company with M. Edward Hoffmann of Finland, a representative of a Finnish newspaper, placed a wreath on the tomb of the "immortal Jenner," whose remains lie interred in the chancel of Berkeley parish church. Dr. W. R. Awdry of Berkeley showed the visitors (who had journeyed expressly from Russia to place the wreath) his collection of Jenner relics. The vicar of Berkeley also received them at the Chantry, where Jenner lived.

The Midwives Act in Cornwall.

At a meeting of the Cornwall midwives committee held at Truro last week it was decided severely to reprimand a certificated midwife. It was reported that an inquest was held in April last at Crowlas upon the bodies of two children, aged two and seven days respectively. The certified midwife who attended the mother in her confinement told the parent that there was no need to call a medical man for the children, although they appear to have been in a weak condition, and the midwife eventually gave a certificate stating that the infants were of premature birth. The children were buried as a consequence of this certificate. The jury returned a verdict to the effect that death was caused by congenital inanition and want of attention, and they desired the coroner to report the case to the midwives committee.

Bristol General Hospital.

The late Mr. R. Bligh has bequeathed £656 to the funds of the Bristol General Hospital.

Dawlish (Devon) Cottage Hospital.

A house-to-house collection was recently made at Dawlish in aid of the funds of the local cottage hospital, and as a result over £100 were raised for the charity.

Cornish Centenarians.

Mr. R. Peter, J.P., solicitor, of Launceston, celebrated his 100th birthday on Oct. 9th. He received congratulations from the King and the Prince of Wales.—The death occurred on Oct. 7th of Mr. James Carne, of St. Columb Minor, the oldest parish clerk in England, who celebrated his 103rd birthday in May last.

Oct. 19th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Neglect of Children.

THREE cases of child neglect came before the city magistrates the other day. A single woman who had given her eight weeks old child opium, presumably to keep it quiet, was sent to gaol for six months. Every facility seems to be afforded for obtaining opium, and it is a favourite remedy for fractiousness or the pitiful wailing of a baby in pain. The other cases were of men, one of whom was sentenced to six months' imprisonment on a charge of neglect. He was, it may be hoped, an unusually marked example of the human brute, for in addition to neglect the man had "brutally kicked his little boy because he had attempted to stop defendant striking his wife." Such men seem uninfluenced by ordinary punishment, and after trying and failing with the good counsel and the ministrations of the chaplain it may be found that one touch of primitive nature in the shape of the "cat" may influence their moral nature. The other case was considered deserving only of three months' imprisonment. These are only samples of what takes place every day, and show that all the efforts of our educational system, all our so-called civilisation does not encessarily suffice to get rid of the savagery of the free-born Englishman.

Cheshire School Children.

An interesting report on the medical inspection of school children at Stockport, from Jan. 7th to the end of July, has been issued by Dr. H. E. Corbin, medical officer, and Dr. A. G. Caldwell, medical inspector. 3920 children were A. G. Caldwell, medical inspector. 3920 children were inspected, of whom 1934 were males and 1986 females. Of the 3920 examined, 2340, or 59 per cent., were notified for various defects. Dirty heads, 596; mouth breathing, 812; eye diseases and defective vision, 1165; ear diseases and deafness, 187; heart diseases and anæmia, 301. A considerable number were excluded from school—125 in all—for various ailments; 18 for discharging ears, 65 for ringworm and skin diseases, 10 for chest troubles, 5 for glands in neck (presumably discharging), 14 for eye diseases, 12 for infectious diseases, and 1 for tubercle. The excluded children would not be readmitted until medically certified as fit, by their own medical attendant or by the medical inspector at the town hall. One of the most interesting and important facts brought out was the bad condition of the teeth in the majority of the children. Nearly 80 per cent. had bad teeth, the girls being worse than the boys. It is obvious that bad teeth give rise in many cases to gastric disorder, to eating insufficent or improper food, and to anæmia, due in part to the septic condition of the mouth from caries of the teeth. In most cases there had evidently been no attempt, by even the simplest means, to keep the teeth clean. No doubt improper feeding, especially, as the report says, the eating of too much fresh white bread, had something to do with the bad condition of the teeth. Possibly the attention supposed now to be given in the elementary schools as to simple hygienic measures may lead to instruction being given in the care of the teeth, and the use of the tooth-brush after meals and at With regard to the use of the tooth-brush, even boards of guardians sometimes need instruction. Some years ago a proposal to provide the workhouse children of a Welsh

union with tooth-brushes was, as reported, received by the guardians with loud and derisive laughter and remarks which led to the conclusion that these gentlemen themselves had very little personal knowledge of the uses of the tooth-brush and did not see why workhouse children should be provided at the expense of the rates with what they themselves did not require. Dr. Meredith Young, the chief medical officer under the Cheshire county council, has also just presented an important report on the present system of medical inspection of school children in the county. He shows how important this systematic work is, as there are about 350 schools and 70,000 scholars concerned. In giving an outline of the scheme of medical inspection he says that when developed it will provide for the medical examination of every child attending a public elementary school at least three times during its school life. He points out that among other objects the question as to whether a child is capable of benefiting to the full by the education provided, can be answered, and in the event of physical or mental defect being discovered endeavours can be made to apply preventive or remedial measures. If such means as these are carried out efficiently throughout the kingdom, there should, in the course of some years, be a distinct improvement in the mental and physical condition of the coming generations. More important than anything else almost is the possibility of weeding out the unfortunate class of feeble mental degenerates, and of protecting them during their lives from being injured and being an injury to the community.

Medical Officer's Salary at Hyde.

For months past the question of the borough medical officer's fees has been discussed at the Hyde town council and in committee, with at times a good deal of heat. Two or three months ago it was stated in the council that though his nominal salary was only £80 a year the total amount received from all sources in his public capacity last year was over £400, a large portion of it coming from fees for outside cases admitted to the borough hospital. It has now been decided by the council, on the recommendation of the general purposes committee, that he should be paid a fixed salary of £65 per annum as medical superintendent of the borough hospital, which amount was to cover all cases with the exception of those of small-pox. It was stated by Councillor (Dr.) J. A. Watts, as reported, that under the new arrangement the medical officer would receive a total of £285 per annum "for services which certainly occupied a very inconsiderable portion of his time." Councillor Watts replied to a number of critics, inside and outside the council, who had, he said, complained of his attitude on the question. He denied that there was any personal element in the matter. Without expressing any opinion on the merits or otherwise of the question, or of the ethics of docking a fellow practitioner's stipend, it may be allowable to ask if the councillor considered a large portion of the fees previously received as unearned increment? Such a reason for cutting down the salary of a borough medical officer must be of very rare occurrence. It is said that the discussion on the question was "somewhat heated," so that the medical officer must have had some supporters.

Hope Hospital Dispute.

The deadlock at the Hope Hospital still continues. At the meeting of the Salford guardians held on Oct. 15th it was said that nothing had been done in reference to the vacancies on the medical staff at the hospital, where, "owing to the action of the British Medical Association, who object to the conditions of service there and to the scale of remuneration, it has been found impossible to obtain applicants." Perhaps some result may follow the meeting arranged by the Local Government Board between Mr. A. Fuller, the medical officer of the Board in charge of Poorlaw matters, with Mr. A. B. Lowry, Local Government Board inspector, and a committee of four of the Salford guardians, to confer on the difficulty. In addition to the medical dilemma it is said that the hospital is under-staffed as to nurses, while as a necessary sequence the patients do not receive the attention they require.

Oct. 19th.

BRIDGWATER (SOMERSET) INFIRMARY.—The late Captain J. Chappell has bequeathed £500 to the funds of this institution.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

University of Glasgow: Installation of Professor 1. H. Bryce. THIS week Professor T. H. Bryce was formally installed in the chair of Anatomy by the Principal, Sir Donald MacAlister, K.C.B. Professor Bryce took for the subject of his inaugural lecture "The Teaching of Anatomy in Glasgow." In a short and interesting résumé of the history of the Glasgow chair of anatomy he first noted the remarkable length of tenure of the occupants of the chair. From 1790 to 1909 it had been held by only three professors—James Jeffrey, appointed in 1790; Allen Thomson in 1848; and Emeritus Professor Cleland in 1877. The chair was founded in 1718, and for a hundred years included the professorship of botany. Notwithstanding its specialisation the chair of botany. Notwithstanding its specialisation the chair had always remained one of comparative anatomy, and the ideal of 1720—that university teaching of anatomy involved the teaching of everything that elucidated the structure of the human body—remained. After alluding to the professors who had previously held the chair, Professor Bryce said it would not be appropriate on this occasion to refer in detail to the many publications with which Professor Cleland had enriched anatomical literature. Suffice it that he had occupied the foremost place among the anatomists of his day in respect of the breadth of his scientific horizon. In his gift to the University and to his successors in the chair of his admirable and interesting collection Professor Cleland has left a rich inheritance for which they could not be too grateful. As a teaching museum it was invaluable to the department, and it contained numerous specimens of much scientific value. It contained, amongst other things, a large collection of skulls of the different races of mankind. Professor Bryce then shortly indicated the lines on which he hoped to see the study of anatomy develop. He claimed that the teaching of histology that is, of normal as opposed to pathological histo-logy—would more properly be taught in the anatomical department. He next referred to the paramount importance for the comprehension of anatomical fact, of a study of development, and pointed out that the enormous advances in recent years in the knowledge of the details of human development placed the teacher in an increasingly advantageous position for the demonstration of embryological facts. He concluded by outlining the courses in the different branches of the subject which he proposed to continue or to institute, and explained that his aim would be to combine in his instruction the scientific with the practical ideals of anatomical teaching.

Viotoria Infirmary, Glasgow.

The fourth biennial dinner of the past and present resident assistants of this institution was held in Glasgow on Oct. 12th. Dr. R. Scott Frew, who presided, in proposing the toast of "The Victoria Infirmary," referred to the development of that institution during the 20 years of its existence, and continued: "We are watching with interest the development of a scheme of extended clinical teaching in Glasgow, whereby the vast clinical material of the Royal Infirmary, after lying almost untouched for a matter of 40 years, will at last become available to the students of the Glasgow Medical School. We hope and trust it is only a matter of time till the Victoria Infirmary will be brought into line with the Royal Infirmary and with the Western Infirmary, and we will then feel that our hospital is fulfilling its highest function as a teaching medical school. That time may be delayed, we may not all see it; but whether or not there is one thing we must never forget, and that is that the Victoria Infirmary taught us, and so is entitled to our life-long gratitude." Dr. A. Freeland Fergus, one of the medical directors to the infirmary, suitably replied. The toast of the "Resident Assistants, Past and Present" was proposed by Dr. D. O. MacGregor in a very happy and humorous speech. Dr. Ernest Watt of Hamilton and Dr. Thomas Archibald replied. The secretary, Mr. Grant Andrew, read letters and telegrams from former residents expressing regret at their absence and wishing their fellows an enjoyable evening. These good wishes were reciprocated to all former residents, whether at home or beyond the seas, and finally, on the proposal of Dr. A. N. McLellan, the health of the chairman was drunk with

St. Andrew's Ambulance Association.

The Earl of Dalkeith presided last week at the twentysixth annual meeting of the St. Andrew's Ambulance Association held in Glasgow. From the annual report submitted it appeared that during the past year 7551 calls had been made on the wagons of the association, and the total number of patients conveyed since the formation of the association was now 100,123. In Glasgow alone the number of calls had been 4829 during the year. This represented an average of 13.23 turns out daily, or, leaving Sundays out of the calculation, 15.42. Out of the total 4829 turns out 2489 were to accidents and 2316 to cases of illness. In 174 cases the wagons were not required on arrival. Of the 2489 calls to accidents 778 were from police offices, houses, and stairs; 978 were street accidents; 236 from public works; 178 from docks and wharves; and 94 from railways and stations. Of these cases 2163 were taken to the Royal Infirmary, 953 to the Western Infirmary, 376 to the Victoria Infirmary, and 187 to the Maternity Hospital, the remainder being taken to their homes or other institutions. The wagons covered 21,269 miles during the year. During the past year also the number of certificates of proficiency issued was 5541, making a grand total since the formation of the association of 87,922. The number of medallions issued was 1882, a grand total of 26.109.

Northern Infirmary, Inverness: New Wards for Treatment of Phthisis.

A large gathering was present at the Northern Infirmary, Inverness, on Oct. 13th, on the occasion of the formal opening of new wards for the treatment of phthisical patients. Provost Gossip, chairman of directors, presided, and said that through the philanthropy of a gentleman now deceased-he meant the late Robert Lawrence—the directors had been enabled to complete the new wards. Last year they had made a change in the manner of collecting money for the upkeep of the infirmary. The change agreed upon the upkeep of the infirmary. The change agreed upon was that they should have a house-to-house collection in Inverness instead of, as formerly, giving the public an opportunity of contributing in the different churches on a particular day. The change so far as it had gone had not been entirely disappointing. Dr. A. W. Mackay said that he thought he was safe in saying that they were amongst the first in the United Kingdom of general hospitals to provide separate phthisis wards for the treatment of that disease alone. Mrs. Gossip in a few words formally opened the door of the wards.

University of Aberdeen: Opening of the Winter Session.

The winter session at Aberdeen University commenced on Oct. 14th. The surgical class did not meet until the 15th, when the new professor, Dr. J. Marnoch, was formally introduced to the professoriate and the students. Professor W. Stephenson, as the senior professor, presided, and there was a large attendance of the University staff and of the students. Professor Stephenson said that unfortunately he had again to take the place of a principal. With regard to that, not the Government, perhaps, but undoubtedly the Secretary for Scotland, was taxing their patience very much in not appointing someone to the principal-As to their new professor he had been appointed by His Majesty the King, and under special conditions which had not been previously imposed. That was to say, greater power had been transferred to the University Court to see that the instruction in surgery was not simply in systematic surgery, but that it is combined with clinical instruction. Professor Marnoch, who had a great reception, said that no higher honour could be bestowed on a graduate than to be elected to a chair in his own university. He succeeded a great master of the art of surgery. a master not merely of local but of world-wide reputation. The example set by him was a great stimulus, and it would be his endeavour to aim at the same high ideals and to carry on the work of the surgery department with efficiency. The amount of clinical material had largely increased of recent years, but something had to be done to enable the student to avail himself of those opportunities to a fuller extent. At present the time at his disposal for the purpose was too broken up, but some arrangement whereby more continuous time would be available for clinical study would be to the advantage of the school. Professor Marnoch then proceeded to deliver an address on Cancer of the Breast. Oct. 20th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Surgeons in Ireland: Presidential Address.

THE winter session of the College was opened on Friday, Oct. 15th, when the President, Mr. J. Lentaigne, presented the prizes of the previous session. Before distributing the prizes he delivered, however, an address in which he referred in weighty terms to the grave difficulties in which the school of the College was now involved, pointing out that these difficulties were not the results of fair competition—that is, of greater industry and more successful work on the part of rival institutions—but arose from a political situation which had induced the Government to complete an endowment by State of every other medical school in Ireland except the School of the College, "which had been carefully excluded from Government favours and left absolutely out in the cold." The scandalous injustice and unfairness of this, he said, were so patent that when the Bill for the formation and endowment of the new universities which were to take over and absorb the four existing medical schools in Ireland, outside Trinity College, Dublin, was being introduced, the then President of the College approached the Government with the fullest confidence that the grievances had only to be stated to be remedied, but all the trouble, loss of time, and expense had resulted in nothing for the College save a few highflown and complimentary phrases for the good work done.

The National University and the Students of the Catholio University Medical School.

A meeting of the past and present students of the Catholic University Medical School was held last week in the Gresham Hotel. The chair was occupied by Surgeon-Colonel F. G. Adye-Curran, whose varied experiences as an army medical officer (now retired), an assistant surgeon at St. Vincent's Hospital, and a former governor of the Apothecaries' Hall of Ireland (the oldest, by the way, of all our Irish medical corporations), give him all the qualifications which opportunity can well furnish towards the making of a reliable adviser to the medical student who has through no fault of his own become involved in a difficulty in the progress of his curriculum. The special object of the meeting in question was a discussion of the position of the medical students of the Catholic University Medical School with regard to the establishment of the new National University, in which it has necessarily been merged. After a certain amount of preliminary debate the following resolution was proposed and passed unanimously:—

We, the past and present students of the Catholic University Medical School, with non-University qualifications, respectfully approach the governing body of the National University and request that they will be good enough to take into consideration the position occupied by us at present, and kindly say what concessions they would feel disposed to grant in the event of our taking a medical or dental degree.

It is certain that the authorities of the new University will lend a kindly ear to this request, as some of them, at any rate, are sure to be in personal sympathy with the petitioners, but whether any practical step will follow I should be loth to prophesy. Those interested in the question are cordially invited to communicate with the secretary, "Conjoint Cecilians," Apothecaries' Hall, Dublin.

The Magdalen Asylum.

There is no institution in our Irish metropolis more deserving of public sympathy and support than the Magdalen Asylum, which is to have its special annual "collection made up" on Sunday next. That institution has now for nearly a quarter of a century been engaged in rescuing the fallen victims of sensuality or deceit, often aided, of course, by the incapacitating persuasions of want and drink. A special peculiarity of the victims of the "social evil" in Dublin is that in a country in which sexual morality in the female ranks so high, their fall from chastity is more calamitous and irreparable. The sisters in charge of the Magdalen Asylum exercise every endeavour to restore the self-respect and self-guiding powers to those fallen ones, and the result offers an interesting field of study for the medical observer. In few institutions can the influence of mind on body be more instructively studied. The morbid irritability, the alcoholic cravings, and the gloomy hopelessness of outlook, which had rendered these women absolutely unfit for the occupation of any

responsible position, gradually disappear in presence of sane advice, kindly tendered, and firm control. The arrest of tuberculous invasion is another conspicuous result of these ministrations, so that there is sound medical reason for hoping that the rather heavy debt of the asylum will be wiped out by Sunday's collection.

Coöperation of Government and People in the Hygiene of National Schools.

Evidence of the general diffusion of hygienic education among the people of Ireland and of the combination of creeds and classes in the determination to utilise the same in the interests of future generations has just been offered by the published correspondence between the representatives of the Women's National Health Association and the representatives of the Irish hierarchy. A resolution was passed by the executive of the former body expressing their gratification at the fact that the school managers in connexion with the Roman Catholics, the Church of Ireland, the Presbyterian Church in Ireland, and the Methodist Church had expressed their readiness to make themselves responsible for one-half of the cost for heating and cleaning of national schools, in accordance with a scheme to be worked out in consultation with the Chief Secretary and in response to his suggestion made to the deputation of the Women's National Health Association of Ireland in May last. The executive, while pointing out that no promise of a Treasury grant could be obtained for the commissioners until the opening of the financial year next spring, pledged themselves, "through their branches, to cooperate with any local efforts that may be made to raise the required sum." They expressed the hope, accordingly, that the school managers throughout the country would be. that the school managers throughout the country would show their earnestness "by themselves inaugurating the proposed scheme this winter by spending their proportion of the proposed funds during the winter months, and keep an account of the same, which can be hereafter presented to the Irish Government as an additional argument for obtaining from the Treasury the hoped-for grant of the half of the total amount." The immediate result was the receipt by Lady Aberdeen of a letter from the two (episcopal) secretaries of the general meeting of the Catholic archbishops and bishops of Ireland, thanking her for the resolution which had been passed, and stating that the bishops had already requested the Catholic managers of schools to take steps to find the necessary funds for that purpose. Many regard this incident as one of the most hopeful signs of the present times.

Trinity College, Dublin, and the Royal University of Ireland. It is announced that the board of Trinity College, Dublin, is willing to consider applications from students of the Royal University of Ireland who may wish to receive allowance for their studies in that University, with the object of taking their degrees in the University of Dublin. Many applications of this character, it is stated, are now before the board.

Poor-law Reform.

Since the publication of the Report of the Royal Commission on the Poor-law, as well as the Report of the Irish Vice-Regal Commission on the same subject, a great deal of discussion has been taking place in Ireland. A conference of Irish women guardians discussed in Dublin last week (1) the public assistance committees v. boards of guardians; (2) the position of women on the public assistance committees; (3) the children; and (4) unmarried mothers. The conference was unanimous in proposing direct election to cooption. Strong exception was taken to the fact that if the public assistance authority was established the services of the majority of the 103 women now serving as guardians in Ireland would be dispensed with, as women are not eligible for seats on the county councils, and a resolution was passed urging that, in view of important changes likely to occur in Poor-law reform in Ireland, it is absolutely necessary that women should be eligible for seats on the borough and county councils. There was a feeling expressed that a more comprehensive scheme than any yet suggested should be devised before legislation took place in reference to children, and that to board out all children who came on the rates was impracticable. reference to unmarried mothers, while all agreed that the workhouse was a most undesirable place for such cases, there were differences of opinion how otherwise they were to be dealt with. Opinion was unanimous that the recommendations of the Royal Commission in regard to the Feeble-Minded in this connexion should be carried into effect.

The Medical Session at Belfast.

Work began at the Royal Victoria Hospital, Belfast, for the present winter session (1909-10) on Oct. 14th, when the introductory address was given by Dr. Henry Hanna, assistant ophthalmic surgeon, to the students. In a racy lecture, Dr. Hanna dwelt upon the duty of students taking a practical interest in hospital work. He suggested that a ward should be opened for children and hoped that in the new University of Belfast there would be clinical examinations in ophthalmology. Lectures began at Queen's College on the same day. The lectures in the Arts Faculty of the University will not start until nexth menth. Oct. 19th.

(FROM OUR OWN CORRESPONDENT.)

Naval Boards of Health.

THE Journal Official has recently published a circular issued by the Under-Secretary of State for the Navy relative to the establishment of boards of health in the naval ports. The chief board of health will be located in Paris at the Ministry of Marine and will comprise four civilian members, selected by the Under-Secretary of State, and four naval members, including the inspector-general of the Service de Santé and the pharmaceutical chemist in charge of the analytical laboratory of the central store department of the navy. The chief board of health is acting as a commission of naval hygiene and epidemiology or as a superintending water board. The local boards of health in each port are composed of eight members, including the medical director-general of the health department of the garrison and the medical man or medical men in charge of the bacteriological laboratory of the port. The Journal Officiel has also published directions relative to the examination and surveillance of drinking water supplies.

Sanitary Regulations for Canal Boats.

The Prefect of Police has recently issued a circular regulating traffic on the waterways in respect to sanitation. All boats entering the Department of the Seine and appearing to have come from an infected district will be visited by sanitary officials at places of which the masters will be informed—namely, at the last lock through which they pass before entering the department. The masters will have to present to the sanitary official their permit for the journey, and also the permit handed to them at the first sanitary visit after their arrival in France. There will also be delivered to them a permit to proceed, for which they must obtain an endorsement at certain places mentioned and which they must show to the officials when required. Moreover, no master may bring his boat to a wharf or discharge cargo in the Department of the Seine without supplying proof that he has undergone the requisite visits. In the event of one of the crew presenting doubtful symptoms of illness, the boats are to be provisionally isolated and all communication between them and the shore is to be prohibited until the arrival of the official medical officer.

Relations of Alcoholism to Crime.

At a meeting of the Academy of Medicine held on Oct. 5th M. Vallon, medical expert attached to the Law Courts, reported that he has had to examine 151 individuals charged with homicide or attempted homicide. In this number there were 7 malingerers and 9 persons who were wrongly supposed to be the subject of mental defects. Of the remaining 135 culprits, 120 were males and only 15 were females. With regard to their condition of health, the following conditions were noted: 1 case of pregnancy with mental derangement, 1 case of morphinomania, 2 cases of neurasthenia, 10 cases of delusions of persecution, 7 cases of various states of mental disorder, 11 cases of hysteria or epilepsy, 18 cases of various diseases either supposed or known to have an effect on the brain, 36 cases of mental defect, and 49 cases of alcoholism. M. Vallon said that the cases of alcoholism were more than one-third of the total number of persons charged with homicide. He added that the influence of alcohol as a contributory cause of homicide would be seen to be even greater

if instead of a mere enumeration of accused individuals personally addicted to alcohol an examination were made of the antecedents of culprits classed under other headings. This would show that many epileptics and mental defectives were the children of alcoholic parents. M. Vallon went on to say that acts of extreme violence might be committed not only by habitual inebriates but also by persons in a state of occasional intoxication due to alcohol, in illustration of which he quoted two cases.

The French Congress of Surgery.

The Twenty-second French Congress of Surgery was held in Paris from Oct. 4th to 9th. The introductory meeting took place in the large amphitheatre of the Faculty of Medicine, under the presidency of M. Richelot, the subject of whose inaugural discourse was entitled "Simple Surgery." commenced with a definition of the term, saying that simple surgery was not that which presented itself first to the mind, but that to which one was brought by experience. He considered that a display of instruments ought to be avoided and that the most successful surgeon was the one who made the best use of his fingers and of his good sense. Avoiding useless expenditure on elaborate appliances for securing asepsis, M. Richelot boiled his compresses in an ordinary domestic laundry boiler and immersed his instruments in hot water containing bicarbonate of sodium. respect to the technique of operations, he thought that all the new forms of apparatus for the precisely regulated administration of chloroform presented no real advantage over the old method of administration on a compress in the hands of an assistant who understood how chloroform acted and knew what points ought to be attended to. In fact, he considered that surgical technique was very often overloaded with useless complications having their origin in an excessive desire on the part of surgeons for methods peculiar to themselves. M. Richelot then made a touching reference to the members of the association who had passed away in the course of the year. The principal question on the official programme was the surgery of the arteries. A discussion was introduced by M. Monod and M. Vauverts, and communications were made on this subject by M. Villar, M. Tuffier, M. Psaltoff, M. Doyen, M. Bégouin, M. Brunswic-le-Bihan, M. Amray, M. Reynès, M. Savariaud, M. Princeteau, M. Vidal, M. Tailhefer, M. de Fourmestrame, M. Delagenière, M. Jordan, M. Giordano, and M. Lardennois. Oct. 18th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Proposed General Strike of Resident Medical Officers of Hospitals.

A RATHER unusual threat has been pronounced by the union of hospital medical officers in Vienna as a last resort for the removal of long-standing grievances. The union has notified the managing boards of all the State hospitals in the city that unless certain reforms are actually begun before Nov. 1st the hospital staffs will tender their resignation on this date, with the prospect that four weeks later the hospital wards would be left with only the professors and their two chief assistants to attend many hundreds of patients. This uncompromising attitude has been adopted in consequence of the evident uselessness of petitions of a more conventional nature. As a rule, in the hospitals there are 30 beds assigned to each "Secundararzt," or house physician, who is responsible for the proper care of the patients. He has not only to write down personally the history and the course of the disease, but also to make all examinations, to keep observation on the food, and to do all the administrative writing required in the wards to which he is attached. This, of course, necessitates a good deal of work of a non-medical nature, which is very much resented by the young medical man, as it takes up so much of his time and interferes with attention to the more scientific side of the daily duties. remuneration also is not satisfactory, being only £55 for the "Secundararzt" and from £75 to £90 for the assistant, with lodging, but only with partial board. A few years ago the conditions of medical service in hospitals were worse still, but the salaries had to be raised to their present level on

account of the dearth of applicants for such posts. Several recent occurrences amongst the staff of one of our largest hospitals showed the necessity of insurance against accident and claims for malpractice, but the payment of the insurance fees was refused by the hospital boards. Finally, on the occasion of some disputes between medical and administrative officers the authorities decided in favour of the latter, which brought about such a feeling of irritation amongst the medical men that a sort of ultimatum was The medical officers ask for (1) a clear decision as to the rights and duties of the medical and the administrative staffs; (2) permission for a medical officer to change his ward in the same hospital after three months; (3) the appointment of clinical clerks to do some of the writing; (4) full board for the whole medical staff; and (5) obligatory insurance by the board of the medical officers against claims arising out of their hospital work and against accidents whilst in employment therein. As all these demands involve a considerable expenditure of public money, the position of the boards is a rather difficult one, and they are trying to come to terms by negotiation. Full preparations have, however, been made for the strike, and hardly any medical men would be found ready to replace those who refuse to continue at work under the present conditions.

The Difficulties at the Ophthalmological Clinic.

Since the death of the celebrated Professor Schnabel the clinic which was under his control has been conducted temporarily by the last of his assistants, and the appointment of his successor has given much more trouble than was expected. The senate of the Medical Faculty in Vienna having recommended Professor Hess of Würzburg, Professor Dimmer of Graz, and another gentleman as three suitable persons from whom a final selection might be made great pressure was exerted upon the Ministry of Education to prevent the appointment of the professor from Germany (i.e., Professor Hess) on so-called patriotic grounds. Academic influence was strong enough to overcome these obstacles, and Professor Hess was asked to take over the duties. He came to Vienna, inspected the clinic, and declined the offered position. He has in Würzburg a palace of a clinic, with the very latest equipments required for modern research, whereas he found in Vienna an antiquated ward, without sufficient space for out-patients. Professor Dimmer in Graz then received an invitation, and he also required increased accommodation for the treatment of patients and for research work, but the lack of funds prevented his modest requests from being complied with. In a few years there will be a new clinic which will be a model institution, but this long period of waiting and suspense would be intolerable to an ophthalmologist of high standing, so Professor Dimmer also refused. As the present situation cannot continue, either the Ministry will have to find the necessary money or it will have to accept a man of secondary scientific importance, an alternative which would be more detrimental to the University than the bureaucracy seems to imagine.

Diagnosis of Cerebral Tumours by Means of X Rays.

At a recent meeting of the Neurological Society Dr. Schüller read a paper on the Diagnostic Value of X Rays in Tumours of the Brain. He said that if a tumour of the brain contained salts of lime its shadow might be visible on the screen or plate, but this was comparatively infrequent. More assistance in this respect might be obtained from certain secondary changes produced by the neoplasm—namely, (1) the destruction of the osseous wall of the skull, either local or general; (2) the dilatation of the venous channels of the diploe, which became so marked that they possessed a diagnostic value;
(3) the increased distinctness of the sutures; and (4) the very characteristic increase of the thickness of skull. This thickening was due either to concentric hyperostosis of the walls, or to long excrescences on the inside of the skull. Sometimes the shape of the skull was changed by the new growth. Dr. Schüller said that he had examined 240 cases and has succeeded in making a positive diagnosis in 150 of them; it was remarkable that amongst the 150 positive cases there were 54 with involvement of the hypophysis. He therefore considered that X ray examination of cases of intracranial mischief was indispensable.

Oct. 18th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

The Prevalence of Plague.

THE plague returns for the week ending Sept. 11th show 2096 deaths compared with 1952 in the week preceding. Bombay Presidency reported 617, Madras 140, Bengal 37, the United Provinces 429, the Punjab 47, Burma 49, the Central Provinces 434, Mysore State 176, Central India 114, and Rajputana 3. After a visitation lasting for more than a decade it has to be confessed that human effort has had little tangible effect on the plague epidemic. In the Punjab last year the death-rate from plague was only slightly higher than that from small-pox, and as this year the returns have been even more favourable there is good ground for hope that the disease is gradually dying out. The plague staff is still as zealous as ever, and the people are generally about as indifferent as they have always been. In a recent report dealing with Northern India, Sir Louis Dane, Lieutenant-Governor of the Punjab, is of opinion that the decrease in mortality can neither be attributed to inoculation, nor to the destruction of rats, nor to the absence of rainfall last autumn. In fact, human agency has had very little to do with it, and all that can be removed from the land. But although no very positive results can be attributed to preventive measures, those measures have been amply justified. It may not be possible to prove by statistics that preventive work has sensibly reduced mortality, but it is quite certain that many cases have occurred in which the efforts of the plague staff have limited the area infected and brought help and encouragement to the suffering people. Moreover, though among an ignorant and prejudiced peasantry it was impossible to carry out scientific preventive measures effectively, a start has been made in the sanitary education of the masses that may be of incalculable value as time goes on.

The Health of Bombay.

A warm fine break in the weather at this time of year, which drives the poorer classes out of their unwholesome dwellings at night to sleep in the open air, always leads to a diminution in prevalence of plague. Consequently the feature of the health returns in Bombay (city) this week is a lower rate of plague deaths, and the drop in the mortality from that cause amounts to no less than two-thirds of last week's total. Only 9 deaths were registered—a figure which is phenomenal for the time of year. Last year in the corresponding week plague accounted for 25 deaths, the mean for five years is 36, and the figure returned a week ago was 27. So decided an improvement makes the prospect of plague dying out altogether at least a hopeful one. Small-pox deaths last week were nil, but cholera is still about, the deaths last week, including several imported cases, being 22. The total mortality from all causes for the week was 591, as against 602 in the previous week, 581 in the corresponding week of 1908, and a quinquennial mean of 671.

Malarial Fevers in the Punjab.

During the last four months of 1908 460,000 deaths from fever were reported in the Punjab, and it is estimated that a quarter of the total population of the province suffered from malaria. Strenuous efforts were made to distribute quinine among the people, and where a regular system of weekly or bi-weekly dosage was possible the results were most satisfactory, almost complete immunity from fever being secured. The epidemic disorganised the whole province, and the Lieutenant-Governor in a recent note urges the cardinal importance of being well prepared to meet a similar calamity in future. Plans prepared with forethought and the organisation of an effective quinine-distributing agency may be the means of saving thousands of lives.

The Malarial Conference.

The following officers from the Central Provinces will attend the Malaria Conference at Simla next month: Mr. Fox-Strangeways, C.S.; Major W. H. Kenrick, I.M.S., Civil Surgeon, Raipur; and Roa Bahadur Madholkar.

An Indian Regiment for Daoca.

Lord Morley has sanctioned the location of half a battalion of an Indian regiment at Dacca and the strengthening of the

military police. The construction of cantonments begins forthwith.

The Indian Medical Service.

In a recent leading article the Pioneer thinks that the popularity of the Indian Medical Service is steadily on the wane, and that candidates are not forthcoming in anything like the numbers that were formerly recorded. At the last examination for commissions there were 48 competitors for 21 vacancies, a proportion of something over 2 to 1; whereas not so many years ago the figures were 7 or 8 to 1. At the same time there is far more desire shown to enter the Royal Army Medical Corps, for at the same examination 54 candidates competed for 20 commissions, the old proportion being at the rate of about 3 competitors for every 2 vacancies. The proposal of the Secretary of State to introduce independent practitioners into India and to allot to them some of the professional appointments and civil surgeoncies has been adversely criticised in the service papers at home, and this suggested introduction has doubtless had its the students in the various colleges. effect upon They see that a career in India no longer offers the chance of lucrative practice apart from professional distinction, and that there will be few compensations in the future for continuous service in a tropical climate. the other hand, the Royal Army Medical Corps is in high favour. At a recent prize distribution of the Royal Army Medical College Sir Frederick Treves remarked that the probationers were entering the service at a very auspicious moment. Addressing them he said: "You know, perhaps, that the Army Medical Department has passed through a period of low water; you enter it on the crest of the flood tide, and on that tide you will be carried to what, I hope, will be fortune. I do not hesitate to say that there is no branch of the service better paid than the Army Medical Service." Sir Frederick Treves linked the two services together when dwelling upon the opportunities offered for advancing and elaborating sanitary science, and for investigations into tropical diseases. The Government of India have yet to make a final pronouncement in respect of independent practitioners, and they should note the change that has taken place in the matter of competition for the Indian Medical Service in this country.

Service Notes.

Major F. L. Blenkinsop, I.M.S., has been appointed staff surgeon, Secunderabad. Captain W. H. Cazaly, I.M.S., on reverting to military duty, has been appointed to the permanent medical charge of the 125th Napier's Rifles. Captain H. C. Buckley, I.M.S., has been appointed to the substantive medical charge of the 17th Infantry. Captain E. A. Roberts, I.M.S., has been appointed to the 67th Punjabis.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Race Suicide: Infanticide in Sydney.

THE city coroner for Sydney has lately expressed himself strongly on the prevalence of infanticide in Sydney, and has made a number of recommendations to mitigate the evil. He advocates an amendment of the law to enable officials to trace all births and the cause of death. A tax on bachelors is proposed and a bonus to parents of large families. The limitation of families is almost confined to parents in easy circumstances. He continues: "As a rule the avoidance of the cares of maternity, the excessive desire for social gaiety, and the mode of life generally (including the diet of parents) are, I believe, the chief causes of small families. On the other hand, the poorer classes, living on plainer diet and leading a more natural life in all respects, continue to have large families. It would seem that the humbler the walk in life the more prolific are the parents. If the present practices continue the whole political control of the State must fall into the hands of the working classes. In my opinion, no State can be prosperous in the widest acceptance of the term if ruled by one class."

Talbot Milk Institute.

The first annual meeting of the Talbot Milk Institute of the Women's Medical Association, Dr. W. P. Norris, Dr. was held in the Melbourne town hall on August 18th, Lady Burnett Ham, and Dr. J. W. Barrett, to assist the Director of

Gibson Carmichael presiding. Dr. A. Jeffreys Wood described the plan of the work, which was modelled on that of the Gouttes de Lait in France. The milk was produced by tuberculin-tested cows, and was at once cooled to 40° F. and despatched to the Willsmere milk depôt for pasteurisation. Owing to the difficulty of keeping any milk sound in the hottest weather the institute had supplied small ice-chests at a cost of 7d. per week to those houses in which the milk was Two nurses were employed in house visitation, being used. and sick children were attended twice a day. The price paid by the institute for pasteurised milk, bottled and sealed with paraffin-wax and delivered, was 4d. per pint, while it was sold at 2d. per pint. About 300 infants had been supplied during the summer, and of these only eight had died. The Lord Mayor moved the adoption of the balance-sheet and said that the city council would fully realise its responsibility in affording financial assistance.

Federal Quarantine.

Some dissatisfaction has been expressed with the inspection of oversea mail steamers under the new Quarantine Act. The matter was mentioned in the Federal Senate in connexion with an alleged delay at Freemantle. Dr. Wollaston (Comptroller of Federal Customs) says that as there is only to be one inspection it is necessary to make it absolutely thorough. The fear that mail liners arriving at night would be compelled to wait till next morning for clearance was unfounded. Arrangements could be made to clear them at once.

Opium Smoking.

The Comptroller of Federal Customs recently suggested an increased tax on opium and the devotion of the proceeds to deporting confirmed Chinese smokers back to their native land. The Chinese Empire Reform Association has addressed a temperate letter to the Minister for Customs pointing out that such a procedure would be futile and that an increase of tax means merely an encouragement to smugglers and the extortion of an increased price from the miserable consumer whose plight is only intensified.

Alfred Hospital, Melbourne.

The annual meeting of subscribers to this hospital was held in Melbourne on July 30th. The report showed that 2421 inpatients and 6261 out-patients were treated during the year, besides 949 casualties. These figures are much larger than in any previous year. The death-rate was 8.84 per cent., which was much lower than that for many years. Financially, the position was unsatisfactory. The loss of revenue from "paying" in-patients (now abolished) was £345. A fourth resident medical officer had been necessary to meet the increased work. The chairman said a rebuilding scheme was under consideration and would necessitate an expenditure of £20,000.

Vital Statistics.

The Victorian Government statist in the last year-book estimates the population of Victoria at 1,273,353, made up of 640,180 males and 633,173 females. The increase for the year was 15,173. The feature of the figures is the great increase relatively of females, it being estimated that there are 99 females to every 100 males—a much greater proportion than in any other State. Melbourne is increasing her population at the expense of country districts. The total number of Chinese is only 6815, and of coloured persons other than Chinese, 1273.

New Sanatorium.

On July 1st Sir P. Sydney Jones opened the R. T. Hall Sanatorium for Consumptives at Hazelbrook, N.S.W. The present building accommodates only 16 patients, but provision will eventually be made for 60 beds. The sanatorium has been constructed under the will of the late Mr. R. T. Hall, himself a sufferer from the disease, who obtained such benefit from open-air treatment that he desired to afford others the opportunity to experience similar treatment.

Medical Inspection of School Children.

The Victorian Department of Education has provided under a new Education Act for the introduction of medical inspection of school children. Three medical inspectors are to be appointed at salaries of £550, £450, and £400. An advisory committee has been nominated, consisting of the President of the British Medical Association, the President of the Women's Medical Association, Dr. W. P. Norris, Dr. Burnett Ham, and Dr. J. W. Barrett, to assist the Director of

Education in formulating a scheme for selecting applicants and drawing up a schedule of duties. It is probable that one at least of the appointments will be given to a medical woman.

Medical Temperance Association.

The Victorian branch of the British Medical Temperance Association, though a very small body numerically, has become very active in propaganda work. A series of public lectures has been arranged on alcohol. The lecturers include Professor W. A. Osborne, professor of physiology in the University of Melbourne; Mr. W. Moore and Mr. T. R. Stirling, indoor surgeons to the Melbourne Hospital; and Dr. J. F. Wilkinson, demonstrator of physiological chemistry in the University of Melbourne.

Momorial to Dr. J. Jamieson.

Dr. J. Jamieson, who recently resigned the lectureship in medicine in the University of Melbourne, has been made the recipient of a presentation at the instance of a number of past and present students. Sir John Madden, chief justice of Victoria and Chancellor of the University, handed to Dr. Jamieson a cheque for £135, the gift taking this form at the request of the recipient. Dr. Jamieson suitably and feelingly acknowledged the gift and said he proposed that the money should be handed to the University to be devoted to the foundation of an annual prize in clinical medicine to be known as the Jamieson prize.

Sept. 14th.

Gbituary.

SIR ARTHUR MITCHELL, K.C.B., M.D., LL.D. ABERD.

Sir Arthur Mitchell, who died at his residence in Drummond-place, Edinburgh, on Oct. 12th, was in many respects a man of unusual attainments, and had for more than 50 years occupied a prominent position among the medical profession of the Scottish capital. He was born in January, 1826, his father being Mr. George Mitchell, C.E. His school education was received in Elgin and he afterwards attended the classes in arts and medicine in the University of Aberdeen, where he graduated as M.A. in 1845 and M.D. in 1848. At the outset of his career he gained additional experience by visits to the medical schools of Paris, Berlin, and Vienna, after which he engaged for a time in private practice. Lunacy was the branch of medicine to which he specially devoted himself, after which it might be said that antiquarian research was his favourite pursuit. In 1857 he received the appointment of Deputy Commissioner in Lunacy for Scotland, and during his tenure of this office he became Morison lecturer on mental diseases to the Royal College of Physicians of Edinburgh. He also in 1864 published a treatise on the Insane in Private Dwellings. His predecessor as Morison lecturer was Dr. William Seller, who died in April, 1869. Sir Arthur Mitchell was appointed to the vacancy in the following month, as mentioned in our columns at the time. The subjects of his final discourses, delivered in March, 1872, were the curability of insanity, the medico-legal relations of insanity to will-making, and the effect of consanguineous marriages on the offspring. As Deputy Commissioner in Lunacy he had for his official superior Dr. W. A. F. Browne, whom he succeeded as Commissioner in May, 1870, retaining the appointment until 1895. From 1880 to 1881 he was a member of the Commission on Criminal Lunacy in England, and from 1888 to 1891 he was chairman of the Commission on Lunacy Administration in Ireland. His historical and antiquarian work involved a great amount of original research and special knowledge. A prominent member of the Society of Antiquarians of Scotland, he was Rhind lecturer on archæology from 1876 to 1878, professor of ancient history to the Royal Scottish Academy, president of the Early Scottish Text Society, vice-president of the Scottish Historical Society, vice-president of the Scottish Meteorological Society, and a member of the Universities (Scotland) Commission. In addition to the treatise already mentioned his published works included two on antiquarian or historical subjects, entitled "The Past in the Present; What is Civilisation?" and "List of Travels in Scotland, 1296 to 1900." In 1875 he received the distinction of LL.D. from the

University of Aberdeen, and in 1887 he was created K.C.B. Sir Arthur Mitchell was a man of charming personality, who readily commanded the affection as well as the admiration and esteem of those with whom he was brought into personal relations. In 1855 he married Miss Margaret Houston of Tullochgriban, Strathspey, who died in 1904, leaving a son.

JOHN HERBERT WELLS, M.B., B.S. LOND., M.R.C.S. Eng., L.R.C.P. Lond.

On Oct. 16th, at Ditchling, a village of the Sussex downlands, John Herbert Wells was released from a long and painful illness which he had borne with consummate bravery for nearly 18 months, the day of his death being the eve of his thirtieth birthday. He is not the first man by many to lose his life through taking the hazard of his calling and before the years had been granted him to fulfil his capacities for the service of science, and he would have been the last to have desired undue praise for his uncomplaining sacrifice, but his career is worthy of record, for it was that of a man who brought real advancement to more than one branch of English medicine by his thorough efficiency of hand and mind and by the enthusiasm of his eager spirit.

John Wells was born at Leicester in 1879, his father being Mr. William Wells, of that town, who survives him, and he was educated at the Wyggeston Hospital High School. His one ambition was always to "be a doctor," and before leaving school in his eighteenth year he had passed his London Matriculation and Pre-liminary Scientific Examinations. Coming up to London he gained simultaneously the Huxley scholarship at Charing Cross Hospital and a natural science scholarship at St. Mary's. He chose the latter, chiefly because there were old schoolfellows amongst the St. Mary's students, and was soon appointed in due succession demonstrator of physiology, practical histology, and pathology. Whilst occupying the first of these posts he attracted the attention of Dr. A. D. Waller, the lecturer in physiology, by his powers of steady work and qualities of mind, and the two became associated in studying the action of anæsthetics upon nerve in the microscopic gas chamber and the visible effects of ether and chloroform upon nerve fibres—work which was subsequently published in the reports of the British Association. Of their further joint labours Dr. Waller has written to us: "In 1902-3 we worked continuously together on the action of anæsthetics. He carried out successfully a series of laborious estimations of the amount of chloroform present in the blood of anæsthetised animals, the results of which have been confirmed by those of subsequent observers. I have now before me his report to the British Medical Association giving 18 mgs. per 100 grammes as the anæsthetic amount of chloroform in the blood and 34 mgs. as the lethal amount. The latest experiments of Buckmaster and Gardner give on the same kind of animals values of 20 and 40 mgs. respec-Dr. Waller adds, after paying a warm tribute to Wells's character, "He was a good and faithful worker who would certainly have taken high rank as a pathologist if he had been spared." But after qualifying M.R.C.S. Eng., L.R.C.P. Lond. in 1903, and gaining the clinical medicine prize at his hospital he turned his attention to the wards, and in the next year, having served as house physician to Dr. Sidney P. Phillips, he graduated M.B., B.S., at the University of London with honours in medicine and pathology. He also gained a silver medal in clinical medicine at St. Mary's, having been adjudged proxime accessit for the Cheadle gold medal.

The next two years of his medical life he spent as assistant to Dr. G. N. Caley at Ealing, and of his work there Dr. Caley has sent us a note which we print below. He was extremely successful with his patients, but a man of Wells's fibre could not remain long detached from the laboratory, and in 1906 he joined the department of therapeutic inoculation at St. Mary's Hospital, and speedily showed such a mastery of the principles and of the technique which Sir Almroth Wright was then elaborating that he became one of the most trusted members of a very hard-working band. Like all of them, he never spared himself at his work, which he was accustomed to extend far into the night, performing the prolonged and patient investigations that were necessary for the establishment of sound methods of vaccine therapy, and there

can be no question that this invaluable branch of treatment was advanced materially by his labour. He used humorously to pride himself on not being a genius, but he was always thorough and always level-headed, and there was no more popular man in the labora-Whilst establishing a private practice which grew rapidly, he took special delight in welcoming his friends to the home circle which he had established by his marriage in August, 1906, with Olive Berenice, daughter of the late Mr. Joseph H. Old of St. Merryn, Cornwall. A son was born to them in the following year and a daughter in 1908, soon after he contracted his fatal illness in the laboratory. This occurred about Whitsuntide, when he suddenly developed symptoms of a general bacterial infection whilst away on a holiday. He was able to return to work, but looked poorly, and the diagnosis of his condition was obscure. The bacteria with which he had been working were those of Malta fever, tubercle, streptococcus, typhoid, and glanders, and it was only too plain that he had received an accidental infection with one of these organisms. Chiefly from observations of his opsonic index it became almost certain that it was the latter, although he had no localising symptoms for some little time. By the end of July a deep swelling could be felt in the calf of his leg and he began to suffer from paroxysmal abdominal pain which suggested a focus of infection in the spleen. He was sent into a nursing home to be treated with inoculations of a vaccine prepared from bacillus mallei controlled by daily observations of his opsonic index. Under this treatment his symptoms nearly cleared up; he was very hopeful of recovery and he was able to go down to the country in the autumn. But the extra amount of walking that he then did brought back pain and swelling in his leg, and he had to return home to lie up again before Christmas, since when he has kept his bed except for a few occasional hours. The swelling in the leg was opened in February, and from some grumous material that was emptied the glanders bacillus was grown in pure culture. The wound soon closed, but was followed by great constitutional disturbance, with severe neuralgia in the groin and shoulder and renewed splenic pain, and these symptoms were not markedly affected by continued vaccine treatment. Last May he showed a great desire to be taken into the country, and with the sanction of his advisers he was moved to Ditchling, near Brighton, where he has since remained. For the last two months at least it has been apparent to his friends that he was a dying man, and as the end drew near he prepared for it with the calm courage that has never failed him. A fortnight ago the infection became generalised, foci appearing in the limbs and face, and though he suffered much less pain the final scene could only be regarded as a merciful release. He was buried on Oct. 18th in the presence of a considerable gathering of his hospital colleagues, including the chief for whom his devotion remained unshaken, and who had done everything that man could do to alleviate his distress. Dr. W. H. Willcox, Dr. H. A. Des Vœux, and Mr. H. S. Collier, who had also attended him during his illness, were all present, and a large number of beautiful wreaths were sent from the members of St. Mary's Hospital staff and many of his other friends who were unable to leave London to follow him to his rest.

We have spoken of the capacity for work which John Wells displayed. There remains a word to say about his deeper qualities, and here we fall back upon the words of a great personal friend. "There never lived," he writes, "a kinder or sweeter-minded man, nor ever passed away a braver spirit. His natural nobility underwent a wonderful development beneath a discipline that would have broken many men. Those who were able to spend with him some hours of his long vigil, even when he must have known the shades to be gathering round him, could hardly realise that he was in the grip of a mortal disease. On the days when he was free from pain he was the old bright companion who had never quite lost his boyhood, and he might have been cheerfully nursing a sprained ankle. His patience never failed, and he showed not only a charming courtesy down to the hour of his death to all who had dealings with him, but he took always a shrewd and kindly interest in the happiness of his friends. None who watched his illness can ever forget its example. He never looked back once nor regretted that he had undertaken the work which had hurt him. Had he recovered he would certainly have returned to it, for at first he often discussed plans for future research." For the first

12 months of his illness he read very widely, philosophical works having a special attraction for a mind of considerable general culture. Towards the end he turned less to books, but he never wearied of his friends, to whose visits he used to look forward eagerly. His greatest happiness lay in the devoted attention of his wife who could rarely be persuaded to leave his bedside, and to that mourning lady, as to his parents, such sympathy has gone out as can hardly be clothed in words. In the time to come they will surely find some comfort in the remembrance that though the loss of John Wells has brought them the full measure of the sorrow of man yet in the dignity of his death there was vigorous evidence of human splendour.

Dr. Guthrie N. Caley writes: "During the time that he was engaged in medical practice in this neighbourhood Dr. Wells, by his genial and cheerful disposition and by his ever-ready sympathy, made many friends who deeply deplore his early death. His professional ability soon gained him a good reputation, and his high integrity and upright manly character assured him the confidence of those entrusted to his professional care. His friends will remember him with affection, and his profession will hold him in honour as one who at a time when his life was rich with promise laid it down with manly fortitude as the penalty of his scientific zeal."

ROBERT CREWDSON BENINGTON, M.D., B.S. DURH., M.R.C.S. Eng., L.R.C.P. Lond., L.S.A.

Dr. Robert Orewdson Benington died suddenly from heart failure on August 26th while acting as substitute for a medical practitioner at Gillingham, Kent. His sudden death, which appears to have escaped the notice of his many friends, probably owing to the season at which it occurred, ends a chequered and remarkable career.

Dr. Benington was a student of St. Thomas's Hospital and acted as house physician after becoming a Member of the Royal College of Surgeons of England in 1879. In the earlier years of his professional life he intended to devote himself to gynæcology, and held the post of clinical assistant to the Hospital for Women, Soho-square, and afterwards proceeded to study at the College of Medicine, Newcastle-on-Tyne, and took the M.D. Durh. in 1892, in which year he was a vice-president of the British Gynæcological Society and contributed several papers to the Transactions. He acted as tutor and demonstrator of anatomy in the Medical College of Durham University. After leaving Durham he settled down to practice, but either because of the uncongeniality of his surroundings or a restlessness in his blood he never remained for long in one place. At one time, so we have been informed, he inherited a considerable fortune and abandoned practice. In more recent years he had held medical appointments in South Africa, ascended the Amazon as a ship surgeon, and travelled in a medical capacity in many parts of the world. In his later years he aged very rapidly, but a small competency which remained to him and the intervention of some devoted friends allowed him to devote almost the whole of his time to anthropological researches which have been so abruptly terminated by his sudden death.

Some 12 months ago he was most industriously carrying out, under the direction of Professor Karl Pearson, an elaborate and accurate series of measurements of skulls in the Museum of the Royal College of Surgeons of England and in the Natural History Museum, South Kensington. At a period of life—he died in his fiftyseventh year-when most men shrink from undertaking fresh enterprises, he became an ardent disciple of the modern biometrical school, and sought to apply the new methods to the problems of anthropology in general and craniology in particular. At the moment of his death he had accumulated a vast store of measurements and tracings, which were to form the subject-matter of important papers he intended to prepare, in conjunction with Professor Pearson, during the present winter. He was not only a very modest worker and gentleman, but also a very accurate and orderly one, so that there is little fear of his work being lost, although he has not lived to see the results of his labour published and appreciated.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The death of the following eminent foreign medical man is announced:—Dr. Kornel Chyzer, head of the medical department of the Ministry of the Interior, Budapest, at the age of 73 years.

Medical Rews.

Foreign University Intelligence .-Baltimore (University of Maryland): Dr. Joseph W. Holland has been appointed Assistant Professor of Anatomy.-Berlin: Dr. Ernst Salkowski, who has been for many years at the head of the chemical department of the University Pathological Institute, has been appointed to an Honorary Professorship.—Bologna: Dr. Ulisse Gardini has been recognised as privat-docent of Urology.—Cornell: Dr. J. A. Hartwell has been promoted to the chair of Surgery. Dr. John R. Murlin has been appointed Assistant Professor of Physiology, and Dr. Silas P. Beebe, Assistant Professor of Experimental Therapeutics.—Cracew: Dr. Stefan Horoszkiewicz, privat-docent of forensic medicine, has been appointed Extraordinary Professor. Dr. Leo Glinski has been appointed Extraordinary Professor of Pathological Anatomy and Dr. Wenzel Chlumsky Extraordinary Professor of Surgery. -Florence: Dr. Guido Marchetti has been recognised as privat-docent of Internal Pathology, and Dr. Guglielmo Foa as privat-docent of Hygiene. - Genoa: Dr. Mario Vittorio Maragliano has been recognised as privat-docent of Internal Pathology and Dr. Umberto Parodi as privat-docent of Pathological Anatomy.—Königsberg: Dr. Adolf Stein has been recognised as privat-docent of Odontology.—Lemberg: Dr. Johann Masurkiewicz has been recognised as privat-docent of Psychiatry. Dr. Bednarsky and Dr. A. Szuleslawski, privat-docenten of Ophthalmology, have been granted the title of Extraordinary Professor.—Naples: Dr. Pasquale Castiglione-Morelli has been recognised as privat-docent of Topographical Anatomy and Operative Medicine and Dr. Vincenzo-Patricelli, as privat-docent of Internal Pathology. Dr. Reinhard Dohrn has been appointed to succeed his father as Director of the Zoological Station.—Padua: Dr. Ettore Greggio has been recognised as privat-docent of External Pathology and Dr. Alberto Graziani as privat-docent of Hygiene.— Palermo: Dr. Tebaldo Cimino has been recognised as privat-docent of Urology and Dr. Eduard Carapelle as privat-docent of Hygiene.—Pisa: Dr. Guido Sotti has been recognised as privat-docent of Pathological Anatomy.—Prague (German University): Dr. Eduard Pietrzikowski, privat-docent of Surgery, has been appointed to an Extraordinary Professorship.—Rome: Dr. Andrea Conti has been recognised as privatdocent of Internal Pathology.—Strasburg: Dr. Hans Dietlen has been recognised as privat-docent of Medicine. - Turin: Dr. Giuseppe Serafini has been recognised as privat-docent of External Pathology and Dr. Adriano Ceradini as privatdocent of Bacteriology. - Utrecht: Dr. A. J. P. Van den Brock of Amsterdam has been appointed to the chair of Anatomy.

THE GUILD OF ST. LUKE.—The annual medical service, under the auspices of the Guild of St. Luke, was held at St. Paul's Cathedral on Wednesday evening. The cathedral was well filled, a number of medical men in academic costume after entering in procession being grouped in the centre of the nave. The music was well rendered by a voluntary choir, under the direction of Mr. W. G. Ross, F.R.C.O., who was at the organ, and Mr. S. Herbert Smith. The processional hymns were "Blessed City, Heavenly Salem," and "The God of Abraham Praise." The anthem was Mendelssohn's "Lord, Thou Above art God," and the hymns before and after the sermon were, "O Strength and Stay Upholding all Creation" and a special Guild hymn, "Thou, Whom High in Heavenly Places." The preacher was the Rev. Fr. Waggett, S.S.J.E., who delivered a vigorous sermon from the text of St. Luke v. 12, 13. The offertory, after paying the expenses of the service, was devoted to the College of St. Luke.

A COMPENSATION CLAIM FOR A FATAL LIGHTNING STROKE.—A somewhat singular application under the Workmen's Compensation Act, 1906, was made at the Brighton county court on Oct. 14th. The widow of a farm labourer who was killed by lightning on July 7th applied for compensation from the tenant of the farm. At the time of the thunderstorm the man was engaged cabbage-planting on an exposed part of the Southdowns, near Brighton, and for the applicant it was held that such planting had to be done when the ground was wet or the plants would die, that the soil was naturally damp and heavy, affording an attraction to

lightning, and that while crouching down seeking what little shelter there was the man would be a great attraction to the electric fluid. His honour Judge Scully held that it had not been shown that the man was subject to any special risk more than anybody else who might have happened to be out in the storm; and to say that he was running exceptional risk seemed to be going beyond the bounds of common-sense and reason. His honour found for the respondent with costs.

MEDICAL SERVICE AT BRIGHTON.—The annual service for the medical men and nurses of Brighton and Hove took place on Sunday evening last at the parish church, Brighton. The church was crowded. The special preacher was the Bishop of Lewes and Vicar of Hove, Dr. Hedley Burrows, and he based his sermon on healing on St. Luke xiii., 17. A portion of the offertory goes to the medical charities of the towns.

THE SPREAD OF ANTHRAX.—At an inquest held last week at Warrington upon a workman who had died from anthrax it was given in evidence that the usual washing appliances for the prevention of hide infection were provided at the tannery where the deceased man worked, but that the workmen generally failed to use them. The coroner said that it was desirable for legislation to be passed making the use of such appliances compulsory upon such workers.

A MEDIAL FOR A MEDICAL MAN.—At a meeting of the Camberwell borough council held on Wednesday the Mayor (Councillor W. S. T. Martin), in reviewing the past municipal year in the borough, remarked that during his time in office he had had the great pleasure of conferring the Royal Humane Society's medal for saving life from drowning on Mr. C. A. Sampson of Camberwell and Frederick Devlin, the latter being a boy who had learnt to swim in the municipal baths.

LITERARY INTELLIGENCE.—Messrs. Simpkin, Marshall, Hamilton, Kent, and Co., Limited, will shortly publish the first number of a new review, to be known as "The Local Government Review," which will deal with all the topics affecting county, municipal, district, and parish government and the administration of the Poor-law.—A new edition of "Manual of Military Ophthalmology," by Colonel M. T. Yarr, R.A.M.C., has been published by Messrs. Cassell and Company, Limited.

THE ASSOCIATION OF CERTIFICATED DISPENSERS.—A special general meeting of this association will be held on Monday, Nov. 1st, at 8 P.M., in the Apothecaries' Hall, Blackfriars, London, E.C., for the purpose of considering the following resolution:—

That this meeting desires to express its regret that the Pharmaceutical Society has not yet taken any effective step to make by-laws under the powers conferred by S. 4 of the Pharmacy Act, 1908, relative to the registration of those holding the assistants certificate and others as pharmaceutical chemists, and respectfully begs the Society of Apothecaries to use its best endeavours to see that the intention of the legislature in this respect is carried out without further delay.

All members and others holding the Hall certificate are invited to attend and support the resolution. The clerk to the society, Mr. A. Mowbray Upton, and Dr. F. S. Toogood will address the meeting.

MONMOUTHSHIRE WATER-SUPPLY. — The difficulties which are connected with the water-supply of colliery districts are dependent mainly upon two factors. The increasing number of inhabitants on the one hand necessitates a larger supply, and, on the other hand, the local supply available is decreased owing to the mining operations. Sooner or later, therefore, it is found necessary to go quite outside the area of the coal-field to obtain a sufficient and suitable supply. These factors are prominently in evidence in the western valleys of Monmouthshire, so that a scheme is in contemplation to construct a reservoir capable of holding over 300,000,000 gallons in Brecknockshire and to convey the water to the Monmouthshire valleys. Already a joint outfall sewer is in course of construction for the colliery towns in the western valleys, so that there ought not to be much difficulty in providing a joint water-supply for the same district. The sparse population of Brecknockshire renders the mountainous parts of the county admirable gathering-grounds for water-supplies, and although large tracts are already reserved for the Cardiff and Merthyr corporations

and by the Aberdare district council, there are still left many excellent catchment areas for the supply of other districts.

THE medical officer of health of Barnstaple (Devon) in a report states that about 90 per cent. of the school children in that town require treatment for their

MEDICAL MAGISTRATES.—Dr. W. F. Crosskey, of Lewes, has been placed on the commission of the peace for the county of Sussex.—Mr. Jamieson Boyd Hurry, M.D. Cantab., D.P.H., has been appointed to the commission of the peace for the borough of Reading.

"CHURCH AND MEDICINE" AT GOLF.—An interesting golf match took place recently at Long Ashton, near Bristol, between teams representing "Church and Medicine." It resulted in an easy win for the medical men, who scored 10 points against 21 by the clergy.

THE OGSTON TESTIMONIAL.—The committee in charge of the testimonial to Professor Ogston desires to intimate that members of the medical profession wishing to contribute should send their subscriptions to the honorary secretary, Dr. Mackenzie Booth, 1, Carden-place, Aberdeen, at an early date, as the subscription list must soon close.

PRESENTATION TO A MEDICAL PRACTITIONER. On Oct. 8th, at Kingswood, near Bristol, Mr. C R. Vevai, L.R.C.P. & S. Edin., L.F.P.S. Glasg., was presented with a case of surgical instruments and an address as a mark of respect and esteem on the occasion of his departure for Bombay.

SOUTH-WEST LONDON MEDICAL SOCIETY.—The first meeting of the session was held on Oct. 13th at the Bolingbroke Hospital. Dr. M. Mackintosh read an interesting and amusing paper on "Errors in Diagnosis." The President, Dr. L. S. McManus, and several members joined in the discussion which followed.

THE SEWERAGE OF YEOVIL (SOMERSET).-Yeovil town council has already spent about £40,000 upon sewerage and sewage works for the town, but the results have been very unsatisfactory. The Local Government Board has now sanctioned the borrowing of £27,500 for the purpose of reconstructing the sewerage works.

MEDICO-LEGAL SOCIETY.—The next meeting of this society will be held in the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W., on Oct. 26th, at 8.15 P.M., when the presidential address will be given by Sir John Tweedy, and Dr. F. Graham Crookshank will read notes on the post-mortem examination of bodies found in the river.

In response to a request by the Secretary of Public Health and Charities of the Republic of Cuba the Asylums Committee of the London County Council has granted Mr. T. S. Logan, assistant medical officer of the Epileptic Colony, 12 months' leave of absence without pay in order that he may assist in the remodelling and reorganisation of the State Asylum for the Insane in Mazorra, Cuba.

THE ROYAL INSTITUTE OF PUBLIC HEALTH. Last Tuesday a course of 13 lectures was started at this institute. The course deals with elementary anatomy, physiology, home nursing, the care of children, school sanitation, infectious disease, and domestic and public hygiene, and has been arranged with a view of assisting candidates wishing to qualify for the positions of health visitors, school nurses, and the like. The lectures are also open to women students not intending to enter for the examination. The lectures will be continued on Tuesdays and Fridays at 7 P.M. at 37, Russell-square, W.C. The fee for the course is 1 guinea.

MALAGA AS A WINTER RESORT.—In his annual report, just received at the Foreign Office, Mr. Staniforth, the British Consul, writes: "The excellence of the climate of Malaga is becoming better appreciated, and a larger number of British visitors winter here every season. It is unfortunate that Malaga is not better known for its climatic conditions, which are unsurpassed at any winter resort. There is a demand in Malaga for a really good hotel. The British visitor at present is obliged to put up at Spanish boarding-houses, the only good English family pension being usually full. A British company might find it to its interest to study the matter."

Parliamentary Intelligence.

HOUSE OF LORDS.

WEDNESDAY, OCT. 13TH.

Asylum Officers' Superannuation Bill.

Asylum Officers' Superannuation Bill.

Lord Monk-Bretton moved the second reading of the Asylum Officers' Superannuation Bill, which is designed to provide for superannuation allowances to officers and servants employed in public asylums for the insane in Great Britain and Ireland. He stated that asylum officers and servants would be under an obligation to contribute towards the pensions. He also announced that in committee he would propose an amendment that pensions might be made at the discretion of the local authority, even although the worker had not completed the necessary ten years' service nor had reached the required age of 60 years. He said, further, that the county councils had been circularised in order to obtain their views on the Bill, but very few objections had been forthcoming.

Lord Bellefer said that many of the county councils were anxious that the Bill should be adoptive. The objections to it were wider spread than the noble lord, who proposed the second reading, seemed to realise. It would likely create a considerable charge on the rates, and the rate-payers' position should be fully considered. In his opinion the further consideration of the Bill should be postponed until next session, in order that it might be more fully discussed in the country by all those who

consideration of the Bill should be postponed until next session, in order that it might be more fully discussed in the country by all those who would be affected by it, and a better Bill ultimately brought forward. The Archbishop of CANTERBURY warmly supported the second reading. The principle of the Bill was indisputably right, and in his opinion those who undertook the care of the insane in asylums should be relieved from all anxiety as to their position when their health had been warm out. worn out.

worn out.

The LORD CHANCELLOR remarked that surely their lordships would give the Bill a second reading. It had not been discussed in the House of Commons because there was no opposition to it there. He meationed that the Commissioners in Lunacy were entirely favourable to the granting of superannuation allowances on a fixed scale to asylum officers. The service was a difficult one, and it was important to obtain for the care of the insane the best and most skilled attendants who would not be tempted to go away to some other occupation.

The Earl of HALSBURY argued that asylum officers and servants were entitled to receive pensions, and he warmly supported the Bill.

The Bill was read a second time.

HOUSE OF COMMONS.

MONDAY, OCT. 18rm. Assistant Surgeons in India.

Assistant Surgeons in India.

Mr. Hazleton asked the Under Secretary of State for India whether the senior assistant professor at the Medical College, Madras, and the senior assistant surgeon at the General Hospital, Madras, were Rurasian military assistant surgeons lent to the civil medical department; whether he could state their medical qualifications and salaries, with the salaries of the civil assistant surgeons under them; and whether it was proposed to open these posts to well-qualified Indians.—The MASTER OF BLIBANK civil List that the two officers mentioned are military assistant surgeons; the Secretary of State has no information as to whether they are Eurasians, or as to their medical qualifications; their total emoluments are respectively Rs. 575 and Rs. 255 a month; the civil assistant surgeons in the Medical College, who hold appointments of equal rank, draw either Rs. 250 or Rs. 200 a month. As was stated in reply ose that duly qualified Indian assistant surgeons will not be held eligible for these posts in the event of vacancies occurring.

TUESDAY, OCT. 19TH.

The Reported Case of Beri-beri in Ireland.

The Reported Case of Beri-bert in Ireland.

Mr. Conor O'Kelly asked the Vice-President of the Department of Agriculture (Ireland) whether his attention had been called to the fact that a Norwegian named Obsen, employed at the whaling station on Iniskea Island, in the county of Mayo, was recently admitted to the local hospital in Belmullet, and was certified by the hospital doctor to be suffering from beri-beri; and, if so, is he in a position to state the causes that led to the outbreak of this disease.—Mr. T. W. Russell replied: The department have ascertained that a Norwegian sailor employed in a steamer catching whales off the Mayo coast was admitted to Belmullet Infirmary on Sept. 11th, and on the 12th he was atmasferred to the Fever Hospital. He was discharged as cured on Sept. 21st. He was discharged as cured on Sept. 21st. He was afterwards admitted to the Leith Hospital in Scotland, where he died from inflammation of the heart. No traces of beri-beri were observable.

Tuberculosis in the Public Services.

Tuberculosis in the Public Services.

Tuberculosis in the Public Services.

Mr. SUMMERBELL asked the Prime Minister whether he was aware that during the past ten years 3286 men had been discharged from the Army, 2673 from the Navy, and 1057 men and women from the Post Office, in all 7016 persons, suffering from tuberculosis; that no provision had been made by the Government for the care of such invalids or the prevention of the spread of the disease; and whether, in view of the efforts made by the Government, in the shape of legislation and other measures, to check the ravages of this disease, he was prepared to take action with a view of making provision for the proper treatment of all such cases in the future.—Mr. Hobhouse (on behalf of Mr. Asquite) answered: I understand that the figures stated in the first part of the question are correct. In answer to the remainder of the question, I have nothing to add to the answer given by the Prime Minister on Nov. 11th, 1908.

WEDNESDAY, OCT. 20TH.

Medical Examinations of London University.

Sir William Collins saked the Prime Minister whether he had received any communications from or on behalf of the medical schools of London in regard to the standard of the medical examinations for degrees of London University; and whether he would state the nature of such communications, and what action, if any, he proposed to take

in regard to them.—Mr. Asquitt wrute in reply: I have received communications from the delegates of the London medical schools and other bodies of the character referred to by my honourable friend, and I have forwarded them to the President of the Royal Commission on the London University.

MARRIAGES.

MARRIAGES.

ODELL—MOORE.—On the 14th inst., at St. Mary Magdalene's, Torquay, by the Rev. Canon Ransford, M.A., Vicar of St. Paul's, Upper Norwood, assisted by the Rev. E. P. Gregg, M.A., Vicar of the parish, and the Rev. R. W. Odell, M.A., Vicar of St. Matthews, Brighton, cousin of the bridegroom, William Odell, M.D., F.R.C.S., of Ferndale, Torquay, to Ruth Annie, younger daughter of Joseph Moore, Esq., of "Culross," Torquay.

SWANN—CASSELS.—At the Grand Hotel, Glasgow, on the 18th October, by the Rev. Thos. Currie, M.A., Langside-hill U.F. Church, assisted by the Rev. David H. Tweeddale, M.A., New Leeds U.F. Church, Alexander James Thompson Swann, M.B., Ch. M. Glasg., West African Medical Staff, Northern Nigeria, to Effie Jenima Cassels, L.R.C.P.&S. Edin., L.F.P.S. Glasg., elder daughter of A. B. Cassels, 12, Camphill-avenue, Langside.

DEATHS.

CLIBBORN.—At Bolton-gardens, W., suddenly, William Clibborn, M.D. T.C.D., late of Dorset House, Bridport.

Rotes, Short Comments, and Answers to Correspondents.

EVERY MAN HIS OWN IMMUNISER.

A CORRESPONDENT has forwarded us a copy of The Autocar of Oct. 9th, in which there is an advertisement of an "influenza cure" opens up a new and dangerous field of unqualified practice. of Flux the 'Flu' Cure taken now will render you immune from influenza and its attendant ills during the whole of the It is a bacillus culture, prepared in one of the world's leading bacteriological laboratories. It causes no inconvenience to the user, but is death to any influenza bacillus which attempts the user, but is death to any influenza bacillus which attempts to enter the system. Supplied in two forms, A Preventive, and B Curative. Case £1 is. 0d. Extra tubes 8s. 6d. each. Proprietors-'Flux' Co., 100, Evering Road, N." In the middle of this text is a figure illustrating the "case" referred to, open and containing a glass phial labelled "skin anæsthetic," another labelled "vaccine," and beneath them a hypodormic syringe and needle. Such a flagrant abuse of a valuable method of treatment scarcely needs reprobation, for its danger is apparent. The proprietors of advise their patrons to inject into themselves, with no kind of scientific control, a substance which, if they describe it accurately as a vaccine, is a remedy requiring the greatest skill and technical knowledge in its employment; but we can hardly believe that even the habitual supporters of unqualified practice will be such fools as to inoculate themselves with an unknown stuff. We have not seen the alleged vaccine and have no knowledge of its composition, but if the claim is true that it is supplied by a "leading bacterio logical laboratory" the person supplying it should certainly be asked for an explanation by the responsible directors of that institution. We do not remember a similar exploitation of modern science, although we have been accustomed to some fairly strong claims from unqualified persons. The advertisement should serve as a warning to all laboratories preparing vaccines for responsible firms to take proper precautions as to the ultimate destination of their products.

PREVAILING DISEASES IN BRAZIL.

Mr. Cheetham, Secretary of the British Legation at Rio de Janeiro, in his annual report just received at the Foreign Office, states that the year 1908 was marked by a very serious epidemic of small-pox in Rio de Janeiro, about 6130 deaths occurring in the four months from June to October, and the total of deaths for the year from this cause alone amounting to 8800. The majority of victims were of negro extraction and to a marked degree persons who had neglected vaccination, though every convenience for it was offered by the authorities. Small-pox, it may be stated, is more or less endemic in the cities of Rio de Janeiro, Bahia, Pernambuco, and Pará, and this year there was an outbreak in Maranhão. Though the heat of Rio is often excessive, the climate is salubrious and the yellow fever of former years has, to all appearances, been practically stamped out. This success is due to the exertions of a department organised by Dr. Oswaldo Cruz, which for some time past has been engaged in scientific sanitary work, including the systematic destruction of mosquitoes of the yellow-fever transmitting variety. The "malaristransmitter" must continue to be plentiful in the marshy outlying districts for many years to come. Similar measures have been taken in Santos with beneficial results, the health of both cities having entirely changed during the last few years and sanitary conditions no longer inspiring the dread which they formerly did. In the case of Santos it was largely owing to the draining and reclaiming of pestilential land in connexion with the dock works that the health of the city was so greatly improved. Of the more important Brazilian ports, Bahia, Manãos, and Pará are the only ones now suffering from yellow fever, and in these places the native-born element is apparently immune. Malaria is common along the lowlying coast-belt and salt-pan district between Rio and the extreme south. It is also rife wherever there is marsh and along all the big slow-moving rivers. The Amazon basin is affected throughout and in the upper waters is undeniably bad, more noticeably perhaps in the Madeira-Mamoré and Acre districts, where the railroad workers and rubber collectors suffer intensely. Mosquitoes abound in these parts in myriads, and the mortality is sufficient to produce alarm in the traveller, though it is to be doubted whether the malaria of Brazil anywhere is of so virulent a type as is found in Africa and many other countries. Much of the mortality is due to bad food in sickness and improper care. Of other diseases tuberculosis is the most persistent in its ravages in the cities, being specially prominent in Rio and Pernambuco, where it shows a predilection for the black population. The official statistics of the mortality from this cause in Rio for the five years 1903-07 inclusive show an average of well over 3000 deaths per year, or exactly 4 per 1000 inhabitants. Though much is due to damp and predisposition, the majority of cases are the result of bad housing, bad food, want of air and care indoors, and dirty habits inseparable from the conditions of life prevailing among negroes, mulattos, and the lower classes generally. Dysentery shows

large in the returns from Pernambuco, and beri-beri in Bahia, the latter being, as ever, mysterious in its attacks in the north-east of Brazil. 10 per cent. of the deaths in St. Louis do Maranhão were from beri-beri in the year 1906. Bubonic plague may be regarded as endemic in most of the big cities, Rio, Bahia, Pernambuco, and Pará having each been infected in the course of 1908. There is, however, an unmistakeably steady decrease in this respect in the figures for Rio, which is able to show a decline of mortality from plague from 48.05 per 100,000 inhabitants (or a total of 360) in 1903 to 8.65 (or a total of 73) in 1907. Leprosy and goitre are still to be found in the State of Minas Geraes, the former sporadic and the latter confined to certain negro communities, due possibly to the water and the absence of lime, which is a feature in the geological formation of the greater part of Brazil. Diseases of the digestive organs figure largely throughout the country, these being due in a great measure to the consumption of raw or improperly cooked manice flour. The negro is susceptible to many diseases to which the white man is, comparatively speaking, immune, and it is he who swells the death returns, his numbers becoming gradually decimated in consequence. The following comparisons, taken from the mortality returns of Rio for 1907, will be interesting in this respect:—

						Deaths per 1000		
Africans				 	 	 	168.96	
Spanish Americans				 	 	 	26.25	
Brazilians				 	 	 	21.31	
British				 	 	 	9.08	

The death-rate of many cities, moreover, is also raised by outside patients coming in from the country to the hospitals for treatment and having the misfortune to die there. The highlands of Brazil are extremely healthy, and much of the sickness which at present prevails will doubtless be avoided as time goes on and the prophylactic measures of the capital are extended. Medicinal plants are to be found distributed in the greatest variety throughout the whole of Brazil.

THE USE OF OXYGEN IN WHOOPING-COUGH.

In very grave cases of whooping-cough, where danger is indicated by extraordinary violence and prolongation of the paroxysms with or without indications of commencing broncho-pneumonia, Dr. Weill, clinical professor of children's diseases in the University of Lyons, has been for some years in the habit of using inhalations of oxygen, and finds this treatment, though not invariably successful, far preferable to antipyrin or morphine. The violence of the paroxysms is lessened, though their frequency may not be diminished, the cyanosis disappears, and the child is far less exhausted during the intervals. He says that signs of broncho-pneumonia usually clear up under this treatment. Considerable quantities of oxygen, say 10 or 12 litres, should be given from the commencement of each paroxysm through a funnel-shaped mouthpiece, and if there is any pneumonia this dose should be repeated hourly even while the child is asleep. In one very alarming case where antipyrin and morphine had both failed the child's life was saved by the inhalation of from 400 to 500 litres of oxygen. These observations were published in La Semaine Médicale of Sept. 15th.

"DR. GUILLOTIN."

To the Editor of THE LANCET.

SIR,-A considerable quantity of documents and letters throwing fresh light on the French Revolution have been discovered in Paris in the course of recent years, material that was not known when Carlyle described the events of that social cataclysm. The instrument of death called with grim drollery the "National Razor" and the "Certain Cure for Headache" will be associated for all time with the name of a worthy and humane physician. In truth, Dr. Ignace Joseph Guillotin had nothing whatever to do with the machine which, in the words of Michélet, conferred on him "une gloire macabre et néfaste." Dr. Guillotin welcomed the Revolution and became a member of the Jacobin Club and of the Constituent Assembly. In the tribune of the latter body he proposed that in the new era that had dawned decapitation should always be the mode of inflicting the death penalty in France—meaning execution by the axe. Having made this proposal he quitted public life for ever and devoted himself to the exercise of his profession. The Assembly adopted Dr. Guillotin's proposal and gave it a sinister amplification. An ex-army surgeon, Dr. Antoine Louis, was asked to design an instrument which should cut off a man's head automatically and instantaneously. Dr. Louis, assisted by a German mechanician, promptly produced a decapitator fulfilling the prescribed conditions, and which was known for the first few months as "La Louisette," but so many French people bearing the prenomen or cognomen of Louis or Louise hastened to change their names that the Government decided that the new machine should be called "La Guillotine."

Dr. Guillotin lived in a small street leading out of the Rue St. Honoré and passed safely through the perils of the Terror, the Directory, and the Consulate, dying in 1814, aged 76. It is perhaps not without interest to state that some of the prescriptions written by Dr. Guillotin may be examined in Paris by the curious. For one patient he prescribed a mixture of "rhubarbe" and "sel de Glauber"—by no means a bad combination! According to the testimony of an intimate friend, he never ceased to deplore the hideous immortality thrust upon him.

Some of the records that have lately been disinterred from musty

archives and the lumber room are exceedingly curious. A dyspeptic young man had received the sound medical advice to eat toast instead of ordinary bread, and to spare himself the inconvenience of attending at the baker's shop every morning at 4 A.M. he arranged to receive a week's supply of toast at one time. Unfortunately for him an unexpected domiciliary visit by the police revealed the presence of a quantity of toast in a cupboard—to be precise, there were 13 pieces. The discoverers were aghast with horror. Here was evidently an aristocrat endeavouring by subtle and diabolical means to create a famine in Paris. He was haled before the Revolutionary Tribunal on this charge, tried, con victed, and executed on the same day.

I am, Sir, yours faithfully,

Worthing, Oct. 18th, 1909.

WATKIN W. JONES.

SOME SCIENTIFIC CATALOGUES.

THE Cambridge Scientific Instrument Company has recently published a revised edition of its catalogue dealing with the Cambridge Rocking Microtome, and anyone concerned in the equipment of a physiclogical or histological laboratory will do well to obtain the pamphlet. It contains a complete description of the rocking microtome, which has now been in use for nearly 25 years. The imbedding of tissues in paraffin to admit of their being cut into sections of but a few micromillimetres in thickness has been productive of a wealth of histological and embryological knowledge, and probably all who have worked with a Cambridge "rocker" will allow it the great merits of rigidity, simplicity of design, and accuracy of result, qualities which fit it well for general laboratory and class work. The design of the instrument is too well known to microscopists to need renewed description, and others who desire to become acquainted with it will be well advised to obtain the present catalogue from Cambridge. A list has also reached us from Messrs. H. F. Angus and Co., of 83, Wigmore-street, W., who supply all descriptions of accessories for microscopical work, including the many stains put up in the laboratory of Dr. G. Grübler of Leipzig. Another pamphlet before us comes from France, being issued by Mr. A. Helmreich, electrician, of Nancy. It describes an apparatus invented by Dr. Miramond de Larognette and described as a "radiateur photo-thermique," which is devised to apply light and radiant heat baths to any part of the body. The pamphlet gives a short account of the indications for this kind of therapy, and then proceeds to describe the apparatus which consists of a hollow metal drum bisected, the halves being hinged together so as to form two valves, which can be opened to admit the shoulder, arm, leg, hip, side of the thorax, or any other part of the body. In each valve are three electric lamps. If it is desired to apply heat to the abdomen or spine the valves are completely opened and the instrument laid flat against the body. The pamphlet is fully illustrated and the apparatus which it describes appears to be a useful and portable appliance for the administration of radiant treatment.

AN INTERESTING PHENOMENON.

To the Editor of THE LANCET.

SIR,—I find there are people who, on closing their ears carefully with their fingers, can receive *vocalisations* within their heads—directing, answering, or commenting. I should be glad to know the physiology and explanation of the phenomenon.

I am, Sir, yours faithfully,

Oct. 12th, 1909.

GENERAL PRACTITIONER.

*** This observation is well known to otologists and appears to be due to unusual penetration and perception of sound. We do not know that the physiology of the occurrence has been made the subject of special study. An instrument is now made which enables observers to eliminate this source of error when testing the hearing, especially in cases of unilateral deafness.—Ed. L.

MERCK'S ANNUAL REPORT.

We have received a copy of E. Merck's annual report (1908, Vol. XXII.) of recent advances in pharmaceutical chemistry and therapeutics which is always worth having and keeping since it is a valuable source of reference to recent advances in therapeutics and pharmacology. Not the least advantage about it also is that the chapter and verse in regard to the original papers on the subject are given. We understand that medical men may obtain a copy gratis from the London office (16, Jewry-street, E.C.). The edition, however, is a limited one. The volume contains 348 pages of literary matter, and reading it is certain to repay the practitioner.

THE JUBILEE OF THE CRANLEIGH COTTAGE HOSPITAL.

In our account of the Cranleigh Cottage Hospital (The Lancet, Oct. 16th, p. 1164) the average duration of stay of patients for the period covered by the last annual report should have been printed as 23.3 days instead of 2.33 days.

T. M. will find in the Students' Number of The Lancet (August 28th, 1909, p. 687) full information with regard to post-graduate work. Announcements are made in our columns from time to time when courses of lectures are delivered which are open to medical men free on presentation of their cards. In the same issue of The Lancet, in

other sections, he will find the names of the dermatological consultants and officers at the metropolitan hospitals. The post-graduate work in London is assisted by the moderate fees of those who take out tickets, but individual hospitals seldom or never charge fees to qualified men who were once their students. With regard to the second question we must consult a veterinary surgeon.

COMMUNICATIONS not noticed in our present issue will receive attention

Medical Piary for the ensuing **CA**eek.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

MONDAY.

ODONTOLOGICAL SECTION (Hon. Secretaries—D. P. Gabell, E. B. Dowsett, J. Howard Mummery): at 8 P.M.

Ormond-street (9 a.m. and 2 p.m.), Tothenham (Gynscological, 2.30 p.m.), West London (2.30 p.m.), Central London Throat and Ear (Minor, (9 a.m., Major, 2 p.m.)), St. Bartholomew's (1.30 p.m.), St.

(MIROT, 93 M., MAJOT, 2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Oross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (1° A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-squars (9.30 A.M.), City Orthopsedic (2.30 P.M.), Soho-square (2 P.M.) Children, Gt. Ormond-street (9 A.M., Auril, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor 9 A.M., Major, 2 P.M.).

SATURDAY (30th),—Royal Free (9 a.m.), London (2 p.m.), Middlesex (1.30 p.m.), St. Thomas's (2 p.m.), University College (9.15 a.m.), Obaring Cross (2 p.m.), St. George's (1 p.m.), St. Mary's (10 a.m.), Throst, Golden-square (9.30 a.m.), Guy's (1.30 p.m.), Children, Gt. Ormond-street (9 a.m. and 9.30 a.m.), West London (2.30 p.m.).

At the Royal Bye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed suclusively "To THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTI-FICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or nows paragraphs should be marked and addressed " To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Managor."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES. TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails

to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are :-

FOR THE UNITED KINEDOM.

One Year 21 12 6
Six Months 0 16 3
Three Months 0 8 2
Three Months 0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANGET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address— THE MANAGER, THE LANGET OFFICES, 423, STRAND, LONDON, ENGLAND.

SOLE AGENTS FOR AMERICA-Messrs. WILLIAM WOOD AND Co., 51, Fifth Avenue, New York, U.S.A.

Presidential Address

"TO REDRESS THE BALANCE."

Delivered before the Section of Balneology and Climatology of the Royal Society of Medicine on Oct. 29th, 1909,

BY LEONARD WILLIAMS, M.D. GLASG., M.R.C.P. Lond.,

PHYSICIAN TO THE FRENCH HOSPITAL, SHAFTESBURY-AVENUE, LONDON, W.C.; ASSISTANT PHYSICIAN TO THE METROPOLITAN HOSPITAL, KINGSLAND-ROAD, N.E.

GENTLEMEN, -To the sciences of balneology and climatology it has always been something of a reproach that their use in therapeutics is purely empirical. That, unfortunately, is a reproach the justice of which cannot be gainsaid, and I have thought that I should be doing something to merit the honour which has been conferred upon me in electing me to be the first President of that section of the Royal Society of Medicine which concerns itself with these subjects if I endeavoured in this address to throw some light, however tentative and theoretical, upon the rationale of the methods which we employ-if I attempted, in short, to redress the balance between science and empiricism which has too long shown so decided a bias in favour of the latter.

The science of medicine in general is necessarily so occupied with detail that the constant tendency of its devotees is to miss the broad outlines—we cannot, as the saying is, see the forest because of the trees. In order to obtain a prospect of any value to our present purpose it is essential that we should, in the first instance, at any rate, forget the existence of the trees and make our survey as wide and comprehensive as possible. With this end in view I would first venture to remind you of what, though obvious, is too frequently forgotten-namely, the extent to which man, and more especially woman, is subject to what are called the cosmic influences. It is axiomatic to say that man cannot escape the ascendency respectively of day and night, of forenoon and evening, nor of the cyclical effects of the seasons; and it must be equally apparent to the seeing eye that the lower down in the evolutionary scale we descend the more completely do we find him the slave of these silent, immutable, and relentless forces. So subject, indeed, is primitive man to these cosmic influences, so completely does he hibernate and otherwise conform to the cosmic laws, that the phases of his life sink almost to the level of the alternation of generations which characterises certain insects. higher in the scale he ascends the more independent of these influences does he become, until he arrives at the high state of civilisation in which, so long as his health is preserved. he may be considered as practically beyond their sway. Here I may pause to point out one of the many reasons why woman is, and always must be, essentially and indefeasibly inferior to man, namely, because she is, by reason of her very womanhood, the docile slave of a lunar monthly revolution, from whose tyranny she can never escape.

So long, then as civilised man retains his health he can afford to disregard these cosmic influences. He may defer the principal call upon his digestive powers to the hour when his frame is exhausted and the sun is set; he may do his best work in the night season; he may labour in winter and in summer play; these and other gauntlets of defiance he may cast with impunity in the teeth of the cosmos-but only so long as his health is maintained. No sooner does he fall a victim to disease than he becomes once more the puppet and plaything of the cosmic powers. Obedient to the rhythm of twilight and dawn, his temperature rises by night and falls by day; the hour of sunset enwraps and constricts him as it would a flower, and by the powers of darkness, like a little child, he is dismayed. Though we cannot explain these subtle and ubiquitous agents we are nevertheless obliged, all of us, to submit to them, and the wise amongst us are those who recognise them and turn them to account.

The same may be said of climatic influences. 1 These are, after all, but a subsection of the cosmic influences which become invested with additional weight and added subtlety

¹ Dr. Gaston Sardou: Revue de Médecine, Jan 10th, 1907, L'être Vivant et les Variations du Milieu Extérieur. No. 4498.

when we consider that they include the factors of heredity and environment—the factors, that is, which indelibly stamp upon races, nations, families, and individuals the characteristics which distinguish them from one another. The importance of the part which climatic influences have played, are playing, and are about to play, in the evolution of man towards his higher destiny it is impossible to overlook and would be difficult to overstate. The differences between the white man and the black, between Asiatics and Europeans, between the Latins and the Saxons, between the northerner in each nation and his not far distant southern brother, are admittedly and even obtrusively climatic in origin. Indirectly climatic, through heredity, is the persistence of these differences through every change of individual milieu, and directly climatic are the modifications which change of milieu imposes upon families and races. In illustration of this last point I need only mention the fair skin and the red hair which long residence in northern climes has conferred upon some Jewish families and the stereotyping by the climate of the North American continent of the descendants of the motley crew of its widely dissemblant annual European recruits into the hatchet-shaped face and wiry frame of the Red Indian aborigines. The mills of God grind slowly, but they grind exceeding small, and anyone who will study the effects of the climatic factor in determining racial differences will have no trouble in persuading himself of their reality nor of their inexorable and eternal

When we take the cold and cosmic northern Scot-cosmic only because we are supposing him to be an invalid—and transport him to the shores of the Mediterranean, we are tearing him from the environment which, acting through countless generations, has made him what he is: fair of skin, and of temperament cautious, taciturn, slow, in order to subject him to the environment which, acting through the same period of time, has produced his antithesis, the typical méridional, swarthy, impulsive, voluble, quick. Such a change must obviously involve an alteration in the man's whole being. The nature, as well as the force, of the stimuli to which he normally reacts are changed, and every cell in his body experiences sensations so new as in their sum to amount to a revolution. We have only to consider that his altered environment would in a few generations transform this Scot into that Italian to realise the ferment, one might almost say the chaos, which this sudden transplantation must effect upon the workings of his internal economy. It is as if we were suddenly to place a seaweed in a greenhouse.

We are as yet unacquainted with, we can at best vaguely conjecture, which it is amongst the various elements which go to form what we call climate that takes the leading part in producing or initiating changes so profound. A great French climatologist when asked, "What is climate?" replied, "Humidity." This is true, but in a limited sense only. It is true that humidity supplies the keynote to the subjective effects of climate and therefore to its immediate results (a climate, for example, is sedative or bracing, according to whether its humidity is high or low), but it is not true of its remote or permanent effects. Of humidity it cannot be said that it affords any explanation whatever of the racial and national distinctions which have just been touched upon, distinctions of which, if they are to teach us anything, climatic considerations must take full and explicit cognisance.

To contemplate these distinctions is to be immediately struck by the paramount part played by the element of colour. The widest differences in the degree of dermic pigmentation are associated with the most striking diversities in other directions, osseous, nervous, intellectual, temperamental, and it is not unreasonable to suppose that the factor which produces the one should be to some extent responsible for the others. This factor is admittedly the influence of the sun, to which we may accordingly look for some assistance in explaining the complicated phenomena with which we are at present concerned. To read the riddle of the sun as it affects human beings is a task as much beyond my compass as it is beyond my powers, but this at any rate I would venture to say of it—that the key to that riddle, if it is ever to be found, must be sought primarily in the large, important, and unduly neglected organ which we call the skin.

The functions of the skin, we are told, comprise protection, sensation, secretion, heat-regulation, and respiration. A little consideration will, I think, suffice to persuade us

that it is endowed with at least one other, and that other no less important than any of the foregoing. amount of pigment in the skin varies directly with the degree of sunlight to which its wearers are exposed. A large amount of pigment is thus obviously protective, and the question which immediately arises is, "Protective of what?" Of mere sensation it cannot be: first, because the skin in its power of developing callosities and increasing the growth of hair is already adequately protected in that direction; and, secondly, because ordinary sensation being so unevenly distributed over the integument we should expect the protective pigment to be patchy, even as the protective callosities and protective hairs are patchy, in their distribution. In order to explain the uniformity of pigmentation we must find some function of the skin as a whole which demands protection from the excessive action of the sun's rays, and this, it seems to me, can only be done by investing the integument with the properties of a sensitive plate, stimulation of any portion of which will produce reflex activities in some distant organ. Such a conception has the merit of illuminating some obscure places, and serves in a measure to explain some of the phenomena upon which we are engaged. The pigmentation itself being merely protective, the variations in its degree would necessarily be accompanied by variations more or less constant in other directions, and this we know to be the case. The integument thus becomes the receiving plate for stimuli which are carried to organs which preside over modifications of structure, and of these organs certainly the most important are those glands, the thyroid, the suprarenals, the pituitary, the testicle, and others, the study of whose internal secretions has recently opened up such a wide and fascinating field for physiological inquiry. So far as their importance in the matter of external conformation is concerned, I need do no more than refer to the consequences of the absence of thyroid secretion in the causation of cretinism and most forms of infantilism, and to the responsibility of the pituitary for acromegaly and most forms of gigantism. That cutaneous stimulation provokes a corresponding stimulation of these internal secretory glands, and that one, at any rate, of the purposes of pigmentation is to protect these glands from an excess of such stimulation—such is the view which I am venturing to suggest to you. The considerations in support of this view are many, but time compels me to limit myself to a few only.

It is well known that the white man cannot live for more than a generation or two in the tropics, and it is equally well known that the black man cannot live for more than a generation or two in the temperate zone. In the one case this is due to excessive stimulation from which the fair skin is unable to protect the internal secretory glands; in the other it is due to inadequate stimulation; the feeble and infrequent sun's rays cannot penetrate the pigmented skin in a degree sufficient to keep the glands up to the level of their normal activities. In each case individuals may survive, families very seldom, and races never. It is significant that the individuals among the whites who most successfully adapt themselves to tropical conditions invariably develop a degree of pigmentation which in some cases is truly surprising, and it is pertinent to note that disorders of the internal secretory glands, the suprarenal, the thyroid, and the ovary, are generally characterised by abnormalities of dermic pigmentation.

If, now, we bring the argument down to a particular case and consider the effects of climate upon one of these internal secretory glands, the thyroid, we shall find that the subjects of thyroid insufficiency, as evidenced by rickets, adenoids, noctural enuresis, simple goitre, and some forms of chronic arthritis, preponderate enormously in the temperate zone, and especially in those parts of the temperate zone which are characterised by a cold, damp climate, which is another way of expressing a climate which is conspicuously devoid of sunshine. The same diseases, and others which are almost certainly the results of the insufficient defensive action of these internal secretory glands, are known to occur with obstinate frequency in the poorer populations of the great cities—populations, that is, whose unfortunate state deprives

them of many things, but especially, and markedly and perennially, of the influence of the sun's rays.

I am, however, very far from wishing to suggest that solar stimulation is the only form of stimulation which, acting on the cutaneous sensitive plate, is capable of keeping the glandular secretions at the level of their optimal activities and their normal interbalance. I have little doubt, for example, that the action of the air itself when allowed to reach the integument plays an important part in this matter, and that the preposterous habit of wearing flannel next the skin, which is so common among the inhabitants of cold, damp climates, inasmuch as it prevents the air from coming in contact with the cutaneous surface, is responsible for much of the physical and mental degeneracy which characterises those who descend to this practice.

We may obtain some further support for the view which I am suggesting by considerations drawn from another branch of our work, namely, balneology. And by balneology I must be understood to include massage, heat, light, and the other accessories to balneary treatment proper, of which the spa physician rightly avails himself.

About the year 1840 an ignorant and illiterate Silesian peasant of the name of Priessnitz attained to world-wide reputation as a healer of all forms of disease, acute and chronic, specific and metabolic, medical and surgical, by the employment of methods which we now call hydrotherapeutic. The undoubted success of these methods, more especially in certain classes of disease, led to their study and investigation by serious physicians in Germany and elsewhere, with the result that they have gradually been placed upon a scientific footing. And yet not quite. Much has been done to sift the corn from the chaff, to provide indications and contra indications, to devise improvements and discard superfluities, but up to the present no one has succeeded in offering any acceptable explanation as to the physiological paths by means of which these results are obtained. One, in the pride of his ignorance, will assert that it is all due to change, another that it is the flushing effect of concomitantly ingested waters, a third that it is all a question of suggestion. It is not necessary to take these so-called explanations seriously, and I mention them only for the purpose of pointing out that they contain that element of half-truth which is ever the worst travesty and the greatest enemy of the whole truth. The problems which await solution are serious problems, which cannot thus summarily be brushed aside. We have to explain, and until and unless an explanation is forthcoming, we must continue to suffer the reproach of empiricism to which I referred at the outset; we have to explain, I say, how it is that substantially the same methods of treatment influence such diverse maladies as rheumatism, scrofula, anæmia, neuralgia, obesity, cardiac insufficiency, renal inadequacy, hepatic inadequacy; and even such mutually exclusive diseases as gout and rheumatoid arthritis. The balneary procedures which are employed in these cases are very properly subject to considerable modifications according to the type of invalid and the nature of his malady, but they have, at any rate, this one great feature in common, that they stimulate the cutaneous To say that this stimulation of the cutaneous surface. surface acts by increasing metabolism does not advance us much further, for it does not explain which of the functions of the skin it is which is instrumental in effecting the alteration in the blood-plasma, which is surely the method by which the improvement is ultimately brought about. If, as I have already suggested, we invest the skin with the functions of a sensitive plate receiving impressions, solar, aerial. tactile, thermal, from without, which it transmits as stimuli to the internal secretory glands, the thyroid, the suprarenal, the pituitary, and their congeners, we have at once the key to that improvement in the state of the blood-plasma upon whose cardinal importance in all matters metabolic Dr. Harry Campbell 7 rightly insists.

That we do not know very much about the action of these internal secretions is all too true. We know something about each of them individually, perhaps, but we know little or nothing about the factor in the situation which is in all probability the most important—namely, the interdependence of these secretions and the result of upsetting their normal relations to one another. The difficulties which are liable to

occur at the menopause afford some clue to the importance of this side of the question, but precise information is wanting. The materials at hand are nevertheless sufficient to afford us some assistance. What we know of the thyroid, for example, amply suffices to raise our estimate of its tribute to the blood-plasma to the level of one of the most essential of the many important constituents of that complex fluid. Its complete absence means cretinism in infancy and myxœdema in adult life; that we know, but we are only just beginning to realise the effects upon the organism when this internal secretion, though present in sufficient amount to protect us from these gross and obtrusive diseases, is nevertheless so diminished as gravely to interfere with the normal metabolic processes. I venture to suggest that investigation in this difficult, but highly attractive, field would reveal the fact that many of the diseases which we now regard as having nothing in common except their amenability to balneary therapeutics would be found to be the dissimilar children of the same parent, and that parent thyroid inadequacy.

To illustrate this point, I select the example to which I have already referred—namely, that two diseases which are to all appearances mutually exclusive, namely, gouty arthritis and rheumatoid arthritis, may in some measure at any rate be brought within the same category by regarding them both as due to perversion or insufficiency of the internal glandular secretions. Of rheumatoid arthritis it is necessary that I should premise that I regard the condition so described as liable to be provoked by a great number of causes, that it is in fact not so much a disease as a symptom, and it is therefore necessary that I should specify what in the present connexion I include under this name. The variety to which I wish to refer is that which occurs with such frequency in women at or about the menopause, the variety, that is, to which Nathan has given the name of metabolic osteoarthritis. That this is due to a disturbance of the interrelation between the internal secretions is obvious, and is indeed admitted by all recent investigators; that it is due to a failure of activity on the part of the thyroid is a thesis which has been sustained by numerous observers. in France, and recently very ably by Dr. Ménard of Paris; 10 that clinical results strongly support this pathology of the affection is evidenced by the decided amelioration which ensues from the exhibition of thyroid extract, a matter to which I can add the testimony of my own experience.

In the case of gouty arthritis not only do we find it in subjects who bear the stigmata of thyroid inadequacy, the subjects, that is, of premature baldness, of neuralgize of all sorts, of constipation, but the disease is admittedly one of inadequate metabolism. Now conditions of inadequate metabolism cannot co-exist with a normally acting thyroid, for again, to quote from the elegant and attractive writings of Dr. Harry Campbell, 11 "The thyroid secretion plays the part of a bellows, causing the vital fire to burn more fiercely." Moreover, the admitted causes of gout. an fiercely." Moreover, the admitted causes of gout, an excess of meat foods and alcoholic drinks, are likewise admitted as poisons which gravely depress the functions of

Here, then, are two diseases which, though widely dissimilar in many, and perhaps in the most important, respects, have nevertheless three points in common: both are characterised outwardly by an arthritis, which affects the same joints in much the same manner; both can be shown, and have been shown, to be accompanied by an insufficiency of thyroid secretion; and in both stimulation of the skin by baths, douches, heat, light, produces an amelioration which experience proves to be beyond all question or cavil. There seems to be no escape from the conclusion that, so far as the arthritic element is concerned, the responsibility must rest with the thyroid, nor that the amelioration which all concur in conceding to the balneary procedures is brought about by the stimulation of that gland.

Before leaving the question of the thyroid there are some other facts to which it seems pertinent to refer. The first of these is that since the discovery of radio-activity every spa in Europe has been busily engaged in demonstrating that its

Another point of interest in this connexion is furnished by the relation of the thyroid gland to the salts of calcium. It is known that one of the functions of the gland is to fix these salts in the body, and further investigations into the matter have shown, as indeed one would expect, that the exhibition of these salts stimulates thyroid activity. One of the first signs of increased thyroid activity is diuresis, and I may mention parenthetically that when I was a practising balneologist I learned to gauge the measure of the ultimate success of my prescriptions by the degree of urinary activity which they evoked. Now, in the matter of ingested waters, it has always been difficult to understand why it is that the renal spas, Contrexéville, Vittel, Martigny, Evian, Wildungen, whose waters, chemically, contain nothing more diuretic than small quantities of calcium salts, should nevertheless have the power which they undoubtedly possess of provoking a very largely increased urinary output. In the light of the above-mentioned facts it is evident that this power is derived in a large measure from the stimulation of the thyroid gland which these calcium salts excite.

Of interest also in association with the thyroid gland are those spas which lay claims to the cure of sterility in women. These claims are strongly supported in too many instances to permit of reasonable doubt as to their justice, and Franzensbad, Kreuznach, Rheinfelden, Schinznach, Eaux Bonnes, St. Sauveur, and Salies de Béarn, to mention a few only, all enjoy a reputation in this direction which is unquestionably well founded. Some of them, indeed, include instances which are historical. But here, again, the causative factor has always remained a mystery. Where local douches are employed it is easy to understand that they may be helpful; but then, not only may local douches be employed at home, but local douches were unknown at many of these spas until long after their reputation in the cure of sterility had become firmly established. They have, however, all of them made a special feature of general baths, general douches, and the other methods of stimulating the cutaneous sensitive plate, by which means I suggest that the internal secretory activities are evoked. That it is the thyroid which is chiefly appealed to by such means is rendered probable by the very conspicuous involvement of the skin and its appendages in myxœdema and in degrees less pronounced of thyroid inadequacy. That the thyroid is a gland whose activities are essential to pregnancy is well known, 12 for one of the most efficient means of treating sterility is by properly regulated thyroid treatment, 13 and the reason for this was provided by Gaskell 14 when he showed that the thyroid gland of vertebrates is derived from the uterus of the palæostracean ancestor.

From consideration of the thyroid, too, we may obtain much instructive information concerning another subject which looms large in the purview, not only of every health resort physician, but of every practitioner of medicine, a subject of which it is safe to say that more nonsense of a pseudo-scientific kind has been written than upon any other topic in the whole range of medicine—I mean diet. neither the time nor the place to embark upon a discussion of the matter, but this, at any rate, I am prepared to assert, that the explanation of all the numerous meat-excluding dietaries is based on the fact that their apostles and disciples suffer from diminished activity of the thyroid gland upon which meat foods are known to act so as still further to diminish its activity.

But while thus drawing some illustrations from the thyroid gland, I must not be understood to suggest that this is the only secreto y organ which is stimulated by the various methods under consideration. Such a narrowing of the issue is very far from my intention. The other glands which we include in the same category are probably of at least equal importance, but the available facts concerning

waters contain a certain measure of this peculiar unknown property, quite irrespective of the results which may ultimately be shown to attach to the exposure of the human body thereto. Now, out of the chaos of hypothesis, romance and heroics, which have already encrusted the subject, one fact, and one fact only, has so far emerged, and that is the fact established by a French observer, to the effect that radio-active waters produce an enlargement of the thyroid gland.

them are at present scarcely such as to lend themselves to illustration. A few, nevertheless, there are.

To return for a moment to the question of dermic pigideals are less and less in the direction of curing disease, for

mentation, to which I referred at the outset, it is obvious that, judging from pathology, it is to the suprarenals that we must look for the greatest power in this direction. It is well recognised that when these glands are profoundly disturbed, as in Addison's disease, the fairest of northern skins is made to assume the dusky tint of the mulatto. But the suprarenals do not bear the sole responsibility for pigmentary activity. We know that utero-ovarian disturbance may produce chloasma and that Graves's disease and rheumatoid arthritis are almost invariably accompanied by abnormal pigmentary phenomena. Nor is it, in truth, necessary to interrogate pathology on this subject, for physiology is ready with an illustration which is sufficiently striking. The blood, which we know to be manufactured in some of these internal secretory glands, has a pigment peculiar to itself, and significantly enough its colour is precisely that which is employed by the photographer in order to protect his sensitive plate against the action of the actinic rays of the sun. That one at any rate of the purposes of the red corpuscles is to afford a similar protection to some of the internal organs must be perfectly obvious to anyone who considers the matter. 15

But it is useless to multiply instances of the association of individual internal secretory glands with the subjects with which we are engaged, for I regard as infinitely more important to a true appreciation of the whole question a realisation of the power which these glands exercise over one another. That they stand to one another in a position of physiological antagonism, and that the smooth and sufficient working of each is essential to the prevention of excess or perversion in one or some others, and thus to the plasmic equilibrium of the whole body, is now well recognised by all observers in this field.¹⁶ This reciprocal action of the various internal secretions, this interglandular synergy—the process, that is, by which each contributes its due share, and neither more nor less than its due share, to the blood plasma-constitutes a factor of the utmost importance in the production and maintenance of what we call health, the condition which all can appreciate but none can define. And in my desire to emphasise this aspect of the matter I would venture even further, and suggest to you that in the exact proportional representation of these glands in the individual economy is to be found the secret of those subtle yet salient differences of character and temperament which distinguish the man of action from the man of thought, the scientist from the poet, the ascetic from the voluptuary. That cosmic influences determine the production of certain of these types is suggested by the fact that so many of any particular type tend to appear on the world's stage at about the same time, as witness the Augustan and Elizabethan periods in literature, the Napoleonic in men of action, and the Victorian in men of science; and that climate may have a determining voice in shaping the cosmic influence is rendered probable by the fact that a large proportion of the great men of any particular epoch are drawn from the same country. It is a fascinating, even though it be a futile, speculation to think that with a little more of this internal secretion or, perchance, a little less of that, General Boulanger might have been a Cæsar; that with an infinitesimal difference in the admixture of these clusive essences Charles II. might have been a Puritan. A more practical application of the same idea, more especially having regard to Gaskell's work on the thyroid, is that the determination of sex in the fœtus may be found to be governed by internal secretory considerations.

But to return to the questions of climatology and balneology, from which I have already too widely strayed, it might conceivably be urged that inasmuch as the pharmacist supplies us with reliable preparations of these internal secretory organs, the practice of balneary and kindred procedures will ultimately become displaced by organotherapy. This is a proposition which I find it very difficult to accept. If it is possible to foretell anything about the future of medicine, it is surely safe to predict that in moving away

following an orderly scientific evolutionary movement. Our ideals are less and less in the direction of curing disease, for in its presence, when once established, we realise that we are for the most part merely enlightened onlookers, and our endeavours tend in consequence more and more in the direction of preventing, evading, and forestalling disease. It is our aim rather to correct nascent or acquired tendencies than to cure established ills, and when we have succeeded in educating the public to this view of our mission, the day of the climatologist, and perhaps more especially of the balneologist, will be at hand. Of the medical triumphs of the immediate past, the most conspicuous and encluring are those which have been won in the field of public prevention, and it is my firm belief that the most conspicuous triumphs which await us in the immediate future will be won in the field of individual preven-In this field the most effective weapons are those tion. which we are here to study, to advocate, and, if need be, to defend; and so long as we pursue our ideals in the true spirit of scientific inquiry, so long will this section of the Royal Society of Medicine continue to increase in prosperity and to advance in dignity, in worth, and influence.

THE NEED FOR LEGISLATION IN REGARD TO ANÆSTHETICS, AND THE LINES UPON WHICH IT SHOULD TAKE PLACE.*

By FREDERIC W. HEWITT, M.V.O., M.A., M.D. CANTAB.,

AN.ESTHETIST TO H.M. THE KING; PHYSICIAN-ANÆSTHETIST TO ST, GEORGE'S HOSPITAL; CONSULTING ANÆSTHETIST AND EMERITUS LECTURER ON AN ESTHETICS AT THE LONDON HOSPITAL; LATE ANÆSTHETIST AT THE ROYAL DENTAL

I AM glad to have this opportunity of tendering my best thanks to the Council of this society for the honour they have done me in suggesting that as a visitor I might bring before you the important question of the desirability of legislation in regard to anæsthetics. You will, I am sure, realise that this question has a far wider range than at first sight appears, for it is intimately associated with that greatest of all questions to our profession—the suppression of unqualified practice in general. I do not propose to enter into the causes which have led up to the unsatisfactory state of the department of practice with which I am about to deal. The phenomenal advances which have taken place in surgery proper during the past 30 years have left the problem of safe anæsthesia in the background, and it is only quite recently that a movement has been inaugurated to give this problem the prominence it deserves. Whatever means be chosen to prevent pain during a surgical operation, be it one of the greatest magnitude or one of so-called minor importance, the administrator of the anæsthetic takes upon himself two responsibilities. The first of these is towards his patient, whom he should provide with safety and comfort during what must always be an unpleasant ordeal; the second is towards the operator, whom he should provide with the best possible local conditions for the particular operation. Speaking generally, I would submit that the importance of the anæsthetic as a factor in surgery is not sufficiently realised. Day after day the public mind is perturbed by announcements of deaths under anæsthetics, and yet no united efforts are made to reduce the distressing mortality from these agents. That the mortality can be reduced I most unhesitatingly affirm. I believe, indeed, that had a proper share of attention been devoted to anæsthetics when modern surgery first took form, thousands of human lives would have been saved, and what is almost as important for the future progress and scope of surgery, the acute public alarm which now prevails with regard to anæsthetics, and which obviously is limiting the beneficent work of our profession, would never have become established. And

 loc. cit.

^{*} A paper read before the Medical Society of London on Oct 25th, 1909.

here let me say that the proposals I am about to place before you have as their sole object the interests of the public whom we serve, and that they are not intended to benefit the medical profession, the dental profession, or any special department of either. Experience has proved that the risks and discomforts of anæsthetics may be reduced to trifling proportions by the recognition and adoption of proper principles of anæsthetisation, and that such principles may readily be acquired by the rank and file of our profession.

What is the present state of things as regards the administration of anæsthetics in this country? The fact is that the law allows any person whatsoever to administer an anæsthetic for a surgical operation, provided his intentions are good, and that he performs his task to the best of his abilities. It is also legal for any person first to administer an anæsthetic and then to perform an operation upon the patient he has thus rendered unconscious, provided, as before, that his motives are good, and that he does his best for his patient. I need hardly say that in circumstances such as these numerous fatalities have occurred, particularly amongst the poorer classes. At one inquest it was shown that an advertising herbalist had administered chloroform to a healthy servant girl almost immediately after her dinner, and had himself attempted to extract a tooth. At another inquest upon a girl, aged 17 years, who died under nitrous oxide gas administered by an unregistered dentist, the jury expressed the opinion that an anæsthetic should not be given by an unqualified person—a pronouncement which led to a question being asked in the House of Commons, but to nothing more. At another inquest a quack dentist, whose patient died under the influence of ethyl chloride, gave evidence to the effect that he had used this anæsthetic over 1600 times; that 5 cubic centimetres constituted an ordinary dose; that he did not know what 5 cubic centimetres meant; that he was not guided by the patient's condition but by looking at the bottle; and that he did not know how to perform artificial respiration. As regards the dangers of local anæsthetics such as cocaine and its allies I have only to remind you of a case where an unregistered and unqualified dentist caused the death of a patient by injecting cocaine into the gum whilst he performed a dental operation to prove to you the need of some legis-lative protection for those who from ignorance place themselves in such hands. In those instances in which coroners' juries have committed persons for trial on charges of manslaughter the cases have either been dismissed or the judge, in summing up, has pointed out that the prisoner was fulfilling a useful function amongst the poorer classes. In addition to the dangers to which the public are exposed whilst actually under treatment by unregistered dentists, their lives are not infrequently threatened whilst returning to their homes, or subsequently, by alarming symptoms of cocaine poisoning, by profuse hæmorrhage resulting from reckless extractions, or by septic poisoning, often culminating in necrosis, dependent upon the use of unclean forceps and syringes. Time will not permit me to lay before you documentary evidence in my possession proving the reality of these dangers and the need for legislation. Only last week you may have observed in the public press an instance of a case in which a patient nearly lost his life as the result of unskilful treatment by an advertising dental company. The widespread use by advertising and unregistered dentists and dental companies, not only of local but of general anæsthetics, is, I submit, a matter for the serious consideration of our profession, for it brings into the practices of these dangerous charlatans thousands of persons who, were they not tempted by the expressions "painless dentistry" and the like, would certainly find their way to reputable registered dentists and thus avoid the dangers to which I have alluded. Moreover, the use of anæsthetics by quacks favours the perpetration of many a nefarious surgical procedure and the occurrence of many a surgical disaster. This is seen, not only in the practice of the quack dentist, but in that of the bone-setter. If such irregular practitioners were prevented by law from administering anæsthetics or having them administered for them a lasting benefit would be conferred upon the public, and surgery would be deprived of much of that discredit with which its name is sometimes associated.

Passing to reputable medical and dental practitioners,

we find a state of things which, though immeasurably superior so far as the professional spirit is concerned, leaves much to be desired. This is particularly the case in dental practice. Single-handed anæsthetising and operating are extensively resorted to in provincial towns and country districts. Sometimes the "gas" or other anæsthetic is entrusted to a workroom assistant, a maidservant, or even a page-boy. It would, however, be unfair to throw upon the present dental profession the onus of conditions which came into being in the middle of last century. At the last meeting of the British Dental Association at Birmingham I brought before that association the scheme which forms the basis of my present paper, but I regret to say that the majority of those present were opposed to the reforms suggested. I trust, however, on this occasion, by means of statistics which I have recently been collecting, to supplement the arguments I then brought forward. these statistics I shall presently refer. Coming to general surgical practice I must content myself by saying that a great many improvements in the department of anæsthetics are still urgently required. At some of our hospitals there is a deplorable inadequacy both in personnel and in general equipment in this department. In private practice, particularly amongst the middle and poorer classes, the anæsthetic is often so inadequately given that the surgical success of cases is jeopardised. That there are special circumstances under which the double responsibility of anæsthetising and operating may, and should, be undertaken is obvious. But, as I have elsewhere shown, there is incontrovertible statistical evidence of the danger of such a practice, particularly in the hands of non-medically qualified persons.

If it be the great function of our profession to preserve human life, surely it is high time to take some steps towards improving the conditions under which anæsthetics are administered. The proposition I would here submit to you is that the whole system of anæsthetic administration requires to be reorganised from its foundations. We must start from below and suppress unqualified practice in anæsthetics, or we shall never rob anæsthesia of its present perils to the poorer classes and of that discredit into which it has been allowed to fall. We must call upon our legislature to protect the public by some enactment which will prescribe who shall and who shall not administer an anæsthetic for a surgical operation. of course, no reason whatever why reforms in our hospitals and schools should not be pushed forward pari passu with requisitions for legislation; but until legislation has been secured and the line drawn between those who should and those who should not conduct anæsthesia the safety of the public will be threatened and the position of this department of practice will remain degraded. The administration of an anæsthetic is essentially a medical function, and, as I have before indicated, the question as to who should conduct such an administration is part and parcel of the vital question now engaging the attention of the General Medical Councilthat of the prohibition of unqualified practice in general. But the specific question before us is too pressing to be deferred till the main question assumes concrete form. Anæsthetics are now being used upon such a vast scale throughout the United Kingdom that some legislative enactment concerning them would constitute a fitting instalment to the more comprehensive measure which we hope to see introduced at no distant date. According to the report and appendices of the Unqualified Practice Prevention Committee of the General Medical Council which appeared last year, there are only about 10 of 107 colonies and countries which do not protect the public against unqualified practice, and Great Britain is amongst this 10 per cent. minority. In no less than 75 of these 107 colonies and countries the practice of medicine by those not legally recognised as qualified persons is absolutely forbidden. It is interesting to note that in Germany—the only European country besides our own which does not prohibit unqualified practice—there is a projected Imperial Bill which, if passed, would go a long way towards correcting such an anomaly, and the administration of general anæsthetics is specifically referred to in this Bill. In Austria, moreover, special regula-tions have recently been issued by the Home Secretary with regard to single-handed anæsthetising and operating.

Now although it is generally agreed that there is a good case for legislation in regard to anæsthetics, it must be remembered that it is by no means an easy matter to draft a measure which will bring about the desired objects without interfering with those public and professional interests which deserve to be safeguarded. The General Anæsthetics Bill now under the consideration of the Departmental Committee on Coroners' Law 2 has as its main principle the restriction of general anesthesia, however induced, to legally qualified medical practitioners, although it pro-poses to allow registered dentists in practice at the passing of the Act to continue to administer general anæsthetics if they so desire. At the recent meeting of the British Dental Association at Birmingham I endeavoured to prove that by supporting such a Bill the dental profession, instead of losing anything, would greatly gain, for as no unregistered dental practitioner would be entitled to administer a general anæsthetic or to have one administered for him the services of registered practitioners would be requisitioned on a far larger scale than at present, whilst the improved conditions under which dentists would operate and the reciprocity which would be established between medical and dental practitioners would be greatly beneficial to the latter. With a few exceptions, however, the members of the association who were then present were unable to see their way to support the proposals put forward, maintaining, in a resolution, that registered dentists were fully competent to administer anæsthetics for dental operations. The resolution in question protested "against The resolution in question protested "against any legislation which would make it illegal for registered dentists to administer anæsthetics for dental operations.' It was contended that any such legislation would not be "in the best interests of the public." Now, it seems to me Now, it seems to me that those who were responsible for the drafting of this resolution must either have been unaware of the fact that the great majority of provincial dentists are single-handed, and therefore would, under the policy embodied in the resolution, administer general anæsthetics and also operate, or they must have shut their eyes to the dangers and disadvantages of this practice, accepting these, so to speak, in preference to the alternative policy laid before them
—that of placing general anæsthetics in the hands of
medical men and of ensuring that when a patient is rendered unconscious, even for a dental operation, he shall always have two competent practitioners present. I have elsewhere shown by some striking statistics that the practice of ancesthetising and operating single-handed is highly dangerous and I do not see how any individual or any body of professional men can countenance it. This is one of the main points I wish to place before you this evening. I am glad that the Departmental Committee now sitting is fully alive to this particular danger. Curiously enough the accredited representative of the British Dental Association, when giving evidence before this Committee deprecated the practice in question. More curious still, perhaps, is the fact that a distinguished anæsthetist in attempting to explain to the Committee how, on the one hand, he could support the claims of dentists to administer nitrous oxide, whilst on the other, he could not support the practice of administering and operating single-handed, made the statement that most dentists in the country had partners, by which statement he obviously implied that registered dentists were able to administer anæsthetics for one another. Surely he was in ignorance of the true facts of the case. According to the "Dental Directory" just published, there are no less than 373 small towns or districts in the United Kingdom possessing only one registered dentist each, so that in such towns this coöperation between registered dentists is obviously out of the question.

As regards the conditions of dental practice in larger provincial towns, I have, by the kind assistance of numerous friends, collected some interesting information. The following is an alphabetical list of 48 towns, scattered throughout the United Kingdom, in which inquiries as to the conditions of registered dental practice have been conducted: Aberdeen, Aberystwyth, Armagh, Ballymena, Bath, Bedford, Belper, Boston, Bournemouth, Brighton, Bristol, Brixham, Cardiff, Carnarvon, Cheltenham, Chepstow, Deal, Dumfries, Exeter,

Falmouth, Galway, Gateshead, Gloucester, Greenock, Ipswich, King's Lynn, Kingstown, Leigh (Lancs.), Limerick, Llandrindod Wells, Ludlow, Newton Abbot, Nottingham, Oxford, Paignton, Penarth, Reading, Ryde, Selby, Sleaford, Swansea, Taunton, Teignmouth, Torquay, Tralee, Trowbridge, Truro, and Wick; and the subjoined table gives the results of these inquiries:—

Table showing Conditions of Registered Dental Practice in 48 Towns scattered throughout the United Kingdom, the Population of which varies between 342,388 and 1827.

Total population of the 48 towns	2,138,130
Total number of registered dentists (excluding registered or qualified assistants) in practice in the 48 towns	482
Ratio between registered dentists in practice and population	
Total number of registered dentists in practice by themselves in the 48 towns	352
Percentage-ratio of dentists of Group D to those of Group B	73
Total number of registered dentists in partner- ship in the 48 towns	99
Percentage-ratio of dentists of Group F to those of Group B H	20.5
Total number of registered dentists in the 48 towns practising with registered or qualified assistants (excluding the latter)	31
Percentage-ratio between dentists of Group H and those of Group B	6.5

It will be seen that the population covered by the inquiry is, roughly, 2,138,000; that the registered dentists available for this population (excluding registered or qualified assistants) are 482 in number, or 1 to every 4435 persons; that 352 dentists, or 73 per cent., practise by themselves; that 99 dentists, or 20.5 per cent., are in partnership; and that 31 dentists, or 6.5 per cent., practise with registered or qualified assistants. Even if we add together the dentists in partnership and those practising with registered or qualified assistants (making 130 in all) they only constitute 27 per cent. of the total number. In other words, so far as these 48 towns are concerned, there are no less than 73 per cent. of the registered dentists who, under the present system, must either (a) give anæsthetics themselves and operate; (b) obtain some unqualified person, such as a workroom assistant or a domestic servant, to administer the anæsthetic, both of which practices are admittedly reprehensible; or (c) call in medical men to act as anæsthetists. I leave it to this meeting to decide which is the right and only course to be adopted. It is interesting to note in this connexion that the medical men in practice in the 48 towns above specified number 2108; in other words, that there are in these towns 4.3 medical men to every registered dentist. I have been unable to obtain any reliable statistics as to the number of unregistered dentists practising in these towns, but there is ample evidence to show that the number is a large one. That any hardship whatever would be inflicted upon that one registered dentist with a potential practice of over 4000 persons by placing at his disposal the services of a medical man to administer his anæsthetics seems to me impossible to conceive. I should rather be inclined to believe that, as matters now stand in regard to anæsthetic administrations, his practice is prevented from rising to its proper level. If there is in certain towns, as I am given to understand there is, keen competition between registered and unregistered dentists, surely the association of medical men with the former would help the public to distinguish them from the latter, with whom any such association is, as you are aware, contrary to the regulations of the General Medical Council.

I must here refer to some extraordinary remarks just made by Sir Victor Horsley before an audience largely composed of

dentists and their friends. Under the erroneous impression that he is doing a service to the dental profession, he is, I submit, proposing a great disservice to the public. After mentioning the circumstance that one of our licensing bodies has recently made a course of instruction in anæsthetics an essential part of the dental curriculum—a circumstance which many, I believe, regret, but one which, after all, hardly obliges the recipients of such instruction to administer anæsthetics when they pass out into practice—he proceeds to suggest that dental students should be instructed, at general hospitals, in the administration of ether and chloroform, and that chloroform, if administered by certain methods, is a safe anæsthetic. I feel compelled to put on record my most emphatic protest against such mischievous doctrines. That the medical boards of our general hospitals would sanction the instruction of dental students in chloroform administration for dental operations I very much question, particularly when the conditions of dental practice to which I have just referred are borne in mind. Personally I should regard such an event as retrogressive and in the highest degree dangerous to the public. Everyone who has ever administered chloroform for an operation within the oral cavity knows perfectly well that it is in these very cases that it is difficult or impossible to apply the percentage methods upon which Sir Victor Horsley lays so much stress. Although I may appear to depreciate the work now being done by the dental profession I have no such intention. I simply condemn certain antiquated and dangerous systems under which they are compelled to do that work—systems that short-sighted persons, under the impression that they are furthering the interests of existing dentists, would like to see perpetuated. After the evidence I have laid before you it is, I submit, clear that the advocates of dentists administering general anæsthetics must, under present circumstances, also be the advocates of single-handed anæsthetising and operating, and if we are, in this twentieth century, to encourage dentists to administer chloroform and then operate, I fail to see that our profession is doing its duty to the public in attempting to reduce the present mortality from anæsthesia.

Having dealt with one of the two main objections which have been advanced against the General Ansesthetics Bill I come to the other objection-namely, that the Bill does not propose any legislative protection against local anæs-thetics. This omission was largely due to the difficulty experienced in drawing any hard-and-fast line between the comparatively harmless methods of producing localised analgesia and the more dangerous methods of securing this condition by the injection of cocaine and allied drugs into the tissues of the body. After further consideration on the subject, however, it has been found possible to correct this omission and to modify the General Anæsthetics Bill in the direction indicated. It will be seen that by the subjoined Draft Bill general anæsthetics are, as before, placed in the hands of registered medical practitioners, and that local anæsthetics are placed in the hands of registered medical or registered dental practitioners.

MEMORANDUM.

MEMORANDUM.

The object of this Bill is to protect the public, as far as possible, against deaths arising directly or indirectly from the action of anesthetics—a class of drugs or substances employed for producing either generalised or localised insensibility during surgical, medical, obstetrical, or dental operations, acts, or procedures.

The three following facts indicate the need for this legislative protection: 1. Anæsthetics are for the most part powerful poisons.

2. They are constantly being used upon a vast and increasing scale throughout the country.

3. A considerable and increasing number of fatalities are annually taking place in connexion with their administration.

The promoters of the present Bill are of opinion that the solution of

administration.

The promoters of the present Bill are of opinion that the solution of the problem of reducing the number of deaths wholly or partly referable to anesthetics is to be found in a careful study of the circumstances and symptoms which have attended the deaths hitherto recorded. Such a study seems to them to indicate that anesthetics, when employed for the above-named purposes, should be administered only by certain persons. This Bill therefore proposes to make it a penal offence for any person other than the persons herein specified to administer for the purposes above mentioned either any general anesthetic or any local anesthetic by the means described.

ANÆSTHETICS ACT, 1912.

An Act to Regulate the Administration and Employment of Anæs

theties.

Be it enacted by the King's Most Excellent Majesty by and with the advice and consent of the Lords Spiritual and Temporal and Commons in the Present Parliament assembled and by the authority of the same

1. Any person other than a legally qualified medical practitioner

registered under the Medical Acts who shall wilfully administer or cause to be administered to any other person by inhalation or otherwise any drug or substance whether solid, liquid, vaporous or gaseous and whether pure or mixed with any other drug or substance with the object of producing a state of unconsciousness during any surgical, medical, obstetrical or dental operation, act or procedure, or during child-birth, shall be liable on conviction before a Court of Summary Jurisdiction for such offence to a penalty not exceeding £10 and in the case of a second or subsequent conviction to a penalty not exceeding £20, provided always that a person shall not be liable to a penalty under this Section if in conducting such administration he was acting under the immediate direction and supervision of a legally qualified medical practitioner, or if the circumstances attending the administration were such that he had reasonable grounds for believing and did believe that the delay which would have arisen in obtaining the services of a legally qualified medical practitioner would have endangered life, or if having been registered under the Dentists Act 1878 before the passing of the present Act he conducted such administration for a dental operation, act or procedure.

been registered under the Dentists Act 1878 before the passing of the present Act he conducted such administration for a dental operation, act or procedure.

2. Any person other than a legally qualified medical practitioner registered under the Medical Acts who shall inject, insert, or introduce or cause to be injected, inserted or introduced into any tissue or tissues of the body of any other person through a puncture, incision or other breach of surface any drug, medicament, or substance, whether solid or liquid, and whether pure or mixed with any other drug, medicament or substance with the object of producing a state of localised insensibility to pain without unconsciousness during any surgical, medical, obstetrical or dental operation, act or procedure or during childbirth shall be liable on conviction before a Court of Summary Jurisdiction to a penalty not exceeding £10 and in the event of a second or subsequent conviction to a penalty not exceeding £20, provided always that a person shall not be liable to a penalty under this Section if in attempting to produce or in producing such localised insensibility he was acting under the immediate direction and supervision of a legally qualified medical practitioner, or if being registered under the Dentists Acts 1878 he attempted to produce or did produce such localised insensibility for the performance of a dental operation, act or procedure or if being a bond-fide student in dental surgery or dentistry and acting under the Dentists Act 1878 he attempted to produce or did produce such localised insensibility for the performance of a dental operation, act or procedure.

3. The expression "Court of Summary Jurisdiction" in this Act shall

procedure.

3. The expression "Court of Summary Jurisdiction" in this Act shall have the same meaning as in Subsection 11 of Section 13 of the Interpretation Act 1899. In Scotland it shall mean any Justice of the Peace and also the Sheriff. The expression "the Medical Acts," shall mean the Medical Act 1858 and any Acts amending the same passed before the passing of this Act.

4. This Act may be cited as the Anæsthetics Act, 1912.

The main principle laid before you this evening, that of restricting the use of general anæsthetics to medical practitioners, has been endorsed by the Medico-Legal Society, whose valuable services in connexion with this proposed legislation I am glad to have the opportunity of acknowledging. The principle would also appear to have been endorsed by the Section of Anæsthetics of the Royal Society of Medicine, although when the matter came up for consideration by that section there were, I regret to say, certain members present who could not see their way to support the principle. Reforms such as those I have indicated naturally require time for their consideration, and I look forward with confidence to the day when all members of our profession will see the necessity of some such scheme as that which I have had the honour of laying before you this evening.

ON CERTAIN B. COLI INFECTIONS.

By J. CHARLTON BRISCOE, M.D. LOND., M.R.C.P. LOND., ASSISTANT PHYSICIAN TO KING'S COLLEGE HOSPITAL, ETC.

It has been recognised for several years that in some cases the kidneys act as filters through which the body can free itself of the various organisms which produce diseases, and that bacilli and cocci may be eliminated through the urinary apparatus without giving rise to any definite lesion in that tract. To quote a well-known instance, typhoid bacilli may be found in the urine many years after an attack, the host being otherwise healthy. Occasionally, also, tubercle bacilli may be found in the urine of a person affected with tuberculosis of the lungs or other organs, there being no symptoms referable to the urinary system and no lesion being found there subsequently. This is also true for certain cases of pneumococcic and staphylococcic infections. Among the organisms which are found in the urine those belonging to the bacillus coli group occur with great frequency. This condition of bacilluria has attracted considerable attention during the past years and recently several papers have appeared on the subject.1 These contributions have rather tended to

¹ Bruce Clarke: Clinical Journal, February, 1908. L. S. Dudgeon: THE LANCET, Feb. 29th, 1998, p. 616. C. R. Box: THE LANCET, Jan. 11th, 1908, p. 77.

differentiate a condition of colon bacilluria as a separate entity, whereas the condition ought to be regarded as only a phase of the infection in which separate stages of varying degrees of severity may be recognised: 1. A stage in which there is the passage of pus in the urine which may be either intermittent and obviously derived from a pocket or abscess cavity, or be continuously present, probably indicating a more widespread infection of the urinary tract. 2. A milder stage in which, as a rule, there is a continuous passage of the bacilli into the urine, but without the presence of pus or cells derived from the epithelium lining the tract. 3. A condition in which there are intermittent discharges of bacilli without cells-i.e., some specimens of the urine will contain no organisms, while others will be found to be loaded. The symptoms correspond in severity, and in the milder forms there may be nothing to call attention to the condition.

The route by which these organisms gain access to the urine is still the subject of controversy, but the view that it is by way of the urethra, and so by direct extension, seems to be most improbable. It should be remembered that the B. coli is a constant inhabitant of the intestine, and it has been shown that organisms can pass through the apparently intact wall without leaving any detectable lesion, and this is facilitated by any condition which produces obstruction to the onward passage of the intestinal contents. It is hardly a matter of surprise, then, that a history of constipation is usually found in these cases, or that a large proportion of them should occur in women.

In the cases where pus is being passed there will be no difficulty in recognising the condition, as the cloudiness or deposit, or both, will at once arouse suspicion, but in examining the specimen from an individual who is passing only the bacilli the following points should be noted. 1. As a rule, the urine is rather paler than would be expected from its specific gravity. The specific gravity shows no peculiarities of itself, but on account of the pallor of the specimen the high urinometer reading comes as a surprise. 2. The urine is acid in reaction, often strongly so. specimen is not clear and translucent. A kind of haze is present throughout the whole column of the urine. In some cases a cloud, or even a small deposit, of mucus forms at the bottom of the vessel. A slight haze, such as has been indicated above, is frequently present in normal urine and to detect these cases of bacilluria the following simple method can be adopted. A small piece of filter paper is folded in the usual manner and moistened by allowing some water to filter through it into a clean test-tube. This serves two purposes the filter paper is rendered less pervious and inspection of the filtrate in the tube shows whether the test-tube is clean or This latter point is important, as a dirty tube will give the impression of cloudiness in the contained liquid. A small quantity of urine is then filtered into the test-tube. The filter paper allows bacteria to pass through, but holds back most of the other substances which give rise to turbidity; however, red and white blood corpuscles, fat, and occasionally certain fine precipitates do pass through. A warning is here necessary with respect to urines which deposit urates. If such a urine is filtered while it is warm the paper will hold back the urates which are already precipitated, but as the filtrate cools more will be thrown out of solution and will give rise to a haze in the test-tube. This is, of course, immediately dispersed by heating, but it is simpler to cool the urine before filtering as a part of the routine.

When the urine filters clear, there is no appreciable quantity of B. coli present. If, however, the filtrate is cloudy, the next procedure is to put a drop of the urine on a slide, apply a cover-glass, and examine with the microscope. It is not necessary to use a 1-12th oil immersion lens, for the bacilli can be easily seen by the aid of a 1-6th inch objective and a No. 3 eye-piece. It is advisable to cut down the light in the first instance in order to find the focus, after which as much light as is desired can be admitted. If the B. coli are present they will be seen either as round bodies or as short rods, according as they are floating end on or lengthwise, and they can further be seen to be moving briskly. This is in contrast to the appearance presented by cocci or other substances not endowed with the power of locomotion. In the latter case the small bodies may show some movement, but there is no change of position. Some confusion may arise temporarily from the presence of currents in the specimen, but the movement is then in one direction only,

whereas the B. coli move continuously and in various direc-The application of a little heat will often increase the motility of the bacilli, and it will also be found that the rapidity of movement varies in different specimens. Should the haze not have been due to this condition, the cause will be discovered at the microscopic examination. Two further steps are advisable but not essential. In the first place a large loopful of the urine may be taken by means of a sterilised platinum needle and gently rubbed over the surface of an agar tube, which is then incubated. At the end of 24 hours or less there will be a plentiful growth, which is opaque and white. The margins of this growth are usually markedly crenated in outline. The second investigation consists in making a film either from the deposit found on standing or preferably from the centrifugalised deposit. The film is allowed to dry, fixed by heat in the usual manner, and then stained by Gram's method and counterstained with carbol-fuchsin or neutral red. The B. coli are decolourised by Gram's method and take up the counterstain—i.e., are seen to be stained red by this method. The urine is best examined as soon as possible after it is passed, directions being given that the parts should be cleansed carefully before micturition; if necessary, and more especially in women, a catheter specimen should be obtained. This method of examination of the urine is also of value in the isolation of the organism for the treatment of certain cases of infection where the discharge proceeds from some site other than the urinary tract, is obviously contaminated, and from which it would take some time to isolate the organism. Two of these cases will be mentioned later.

If urine is examined in this manner a surprisingly large number of specimens will be found to contain the B. coli. Most of these occur in women, and some pathologists go so far as to say that in the female this condition is of no importance; certainly there may be no associated symptoms of disease unless constipation is considered as such. At times, however, there will be headache, slackness, and general malaise. Confinement to bed may cause the passage of the bacilli. To illustrate the absence of symptoms the following instance may be quoted. While examining the urines of several young men for another purpose, in order to obtain a normal standard, one specimen was found to be teeming with these organisms. The individual was in perfect health at the time, and although specimens have been repeatedly examined since the bacilli have never again been found. At the Evelina Hospital for Children during a period of six months the urines have been carefully examined with regard to this point, and B. coli was passed in appreciable quantity in 6 out of 145 cases. In two of these there were no special symptoms, in two others there was an associated condition which might have been described as "febricula," and in the remaining two the symptoms were more severe.

As illustrating the correlation of symptoms with the intermittent passage of organisms the following case is of interest. A girl, aged 14 years, is one of my out-patients at King's College Hospital; she suffers severely from intermittent attacks of headache and general malaise, and is, besides, a typical case of postural albuminuria. The attacks last for a day or two, and during these periods large numbers of B. coli are found in the urine, but they are not present in the intervals. At these times the albumin is also in larger quantities and may even be present in the specimen passed on rising. Regulation of the bowels alone has not prevented the attacks. There seems to be a direct relationship between the passage of bacilli, the quantity of albumin, and the symptoms. Neither pus, epithelial cells, nor casts have been found. Under treatment directed against the B. coli the headaches and associated symptoms are diminishing, the bacilli are less frequently found, and the quantity of albumin is becoming less.

The passage of B. coli may occur in persons who are suffering from other conditions and may aggravate the original disease. This was the case in two individuals suffering from pulmonary tuberculosis and in a third case of miliary tuberculosis. In the two former patients there was a rise of temperature with sickness and diarrhea, which had not been present before and which subsided with the disappearance of the abnormal urinary condition. In the third case no difference in the symptoms was produced.

In the next two cases the symptoms pointed mainly to the kidney as being the organ affected. The first is that of a

lady, about 60 years of age, who had for three weeks attacks of pain referred to the region of the right kidney, associated with feelings of general malaise and on two occasions with slight rigors. There was some blood in the urine, at times sufficient to be recognised with the naked eye, and in addition a considerable number of motile organisms, which on examination were found to be of the B. coli variety. No rise of temperature was recorded. The right kidney was palpable and at first slightly tender. Treatment directed against the urinary condition has been successful in relieving her and in getting rid of the organisms from the urine, and there has been no return of the symptoms during the past eight months. The second case was that of a nurse who three months previous to being seen had some frequency of micturition, which yielded at the time to treatment by large doses of potassium citrate. On the first day on which she was seen the temperature was 103° F., the tongue was dry and brown, and some delirium was present at night. From the third to the sixth day she had pain in the right loin, with considerable swelling and tenderness of the right kidney. During these first six days the urine contained at times many different organisms, with pus, blood, and epithelial cells, while at other times there were fewer cells and B. coli in pure culture. The patient was examined under an anæsthetic by Sir W. Watson Cheyne, who detected a cervical polypus. This was removed on the seventh day of her illness by Dr. Eardley Holland. The urine continued to contain the bacilli, but the pus cells gradually disappeared. The presence of this septic polypus explained the varying condition of the urine, which at times was contaminated by the vaginal discharge. The temperature came down to normal on the tenth day, but the kidney remained enlarged and tender for a further period of 14 days. Rapid improvement followed treatment by vaccines, and at the end of two months she was in better health and weighed more than she had for several years previously. A few bacilli were still present in the urine, and it was not until the expiration of three months that they finally and permanently disappeared. During this period treatment was also largely directed against the constipation, which had been rather marked. Both these patients complained of pain in the region of the kidney, and in both that organ was enlarged and tender. In the second case the attention was at first directed to the bladder, but the pain in this area was probably due to the polypus and disappeared on its removal.

The following is a case of quite a different character, but it illustrates the advantage of examining the urine for B. coli and of utilising the same when found. A young married woman, the subject of chronic constipation, was in the seventh month of pregnancy. For two months she had been suffering from a recurrent discharge of pus, mucus, and blood from the rectum, accompanied by severe pain and tenesmus. The motions were, however, passed without pain and formed. There was an evening temperature reaching 101° F. with occasional rigors, and she was steadily losing ground. pus from the rectum contained many and various organisms. The urine drawn off by catheter contained B. coli, but no pus cells. Her medical attendant diagnosed ulceration of the lower part of the large intestine and was able to detect some of the ulcers by rectal examination, though there was no induration round them. A surgeon was called in, and, diagnosing a pyosalpinx opening into the rectum, performed laparotomy. The pelvic organs were found to be normal except that the sigmoid flexure was markedly congested. During the night following the operation the patient was delivered of a seven months child, which only survived for a few days. During the next four days the temperature remained between 102.5° and 103.5°, the patient being in the "typhoid state." An injection of 30,000,000 of the dead organisms prepared from the culture derived from the urine was given. This was followed by marked improvement in the general condition of the patient and by a fall in the temperature to between 100° and 1013. The injection was twice repeated at intervals of a week, each time with great improvement. Rectal irrigation produced a most beneficial effect and was responsible for the ultimate cure of the patient, although a temporary relapse occurred after an interval of three months.

Another case in which the urine was employed for the

and an abscess was opened and drained. As the patient's condition did not clear up satisfactorily a second operation was undertaken for the removal of the appendix. A week later the wound was looking perfectly healthy and there was practically no disharge, but the temperature varied from 101° to 103° F. He was pale, anæmic, restless, and had wasted considerably. A culture taken from the wound was found to be sterile, probably owing to the antiseptics employed in the dressings. The urine, however, contained B. coli, and a pure culture was obtained from which a vaccine was prepared. The first injection produced much general improvement, with a fall in the temperature to 98.8°, which, however, was not maintained, but was succeeded on the fifth day by a rise to 102°. A second injection was given seven days after the first and with a similar improvement, and following the third inoculation after a similar interval the temperature became and remained normal.

The three following cases illustrate a condition of caseation of varying extent due to this organism.

A patient, aged 35 years, had been complaining for years of lassitude and weakness. During time she had been chronically constipated and had been troubled with piles and occasional rectal discharge. one year there had been pains in the pelvic region and right flank which increased in severity during the menstrual periods. She lost weight considerably and began to have an evening rise of temperature. The pain eventually became so severe as to prevent her getting about at all. Examination showed that the pelvic organs were matted together, and the condition was diagnosed as due to tuberculous peritonitis confined to the pelvic region. It is not recorded whether B. coli were present or not in the urine. Laparotomy was performed, and the uterus was found to be bound up with the posterior wall of the bladder and a coil of small intestine in a mass of caseous material. The mass was removed as freely as possible. I was asked to estimate the opsonic index to tubercle and to treat the patient for this condition. The tuberculo-opsonic index, however, proved to be normal on four different occasions. Examination of the prine demonstrated the presence of numerous B. coli, sometimes with and at other times without pus. A careful examination of the microscopical sections of the material removed showed that there was no structure suggesting tubercle. Extensive caseation was present, but everywhere throughout this formation were numerous short bacilli, which did not stain by Gram's method and were not acid-fast. Under general treatment and by vaccines of B. coli derived from cultures from the urine she is now well and at work. During the first 12 months after the operation there were periodic attacks of pain followed by the passage of stitches in the urine with small masses of inspissated pus. These attacks have ceased during the past year and the urine is now free from B. coli. A sinus following the operation communicated with the bladder and allowed the passage of urine for the first three months, and remained in an indolent condition for a year, but is now soundly healed. In this case there was a period of nine months during which bacilli were intermittently passed.

The following case also shows this tendency of the B. coli to form indolent caseous masses. A young girl, who had two years' previously been in King's College Hospital under the care of Dr. Nestor Tirard for tuberculous peritonitis which had completely resolved, was readmitted with some obscure pelvic trouble. There was an ill-defined swelling to the left of the middle line reaching to within 2 inches of the umbilicus. Per vaginam the uterus was normal in size but was fixed. The tumour was attached to the left side and fundus of the uterus. A fixed mass was also felt in Douglas's pouch on the right side. Treatment was directed against constipation and she was sent to a convalescent home for three weeks. On her return she was operated on by Dr. John Phillips. A large mass was found attached to the small intestine, great omentum, and left ovary and tube. This was removed and proved to be an inflamed broad ligament cyst. A similar but smaller cyst was found on the right side and was also removed. Dr. W. d'Este Emery reported that they were of a chronic inflammatory nature and almost certainly tuberculous. Nine days later the stitches were removed, the purpose of isolating the organisms is the following. A young man, aged 20 years, developed an attack of appendicitis. It was considered desirable to operate immediately, weeks after the operation. There was still a temperature

ranging between 100° F. in the evening and normal in the morning. The laparotomy wound was soundly healed but rather painful. Shortly afterwards a swelling formed in this area accompanied by considerable pain and increasing induration. In the course of a week the skin over this swelling became gangrenous and sloughed. On removal of this superficial slough a mass of caseous material was seen which gradually separated out, leaving an ulcer about 1½ inches deep. Microscopically it consisted of granular structureless material containing numerous Gramnegative bacilli. A pure culture of B. coli was obtained from it. The urine was acid and contained numerous B. coli. Under treatment the ulcer healed in the course of six weeks with the exception of a small sinus which even now, nine months after operation, discharges a small quantity of bloodstained fluid at the times of the monthly periods. With this exception she has done remarkably well, and six months after the operation was able to walk several miles a day. This case, like the preceding, shows the chronic and indolent nature of these sinuses left by a B. coli infection. In both cases the organism was easily obtained from the urine and a vaccine thus obtained was used in the treatment. sinuses in both cases were sterile, as shown by inoculation of a culture tube.

In the third case the infection gave rise to a condition which was mistaken for a malignant pelvic tumour. woman, aged 50 years, was admitted into the Italian Hospital, under the care of Mr. T. P. Legg, complaining of inability to pass urine. Examination showed a tumour which extended from the pubes to the umbilicus. Per vaginam this was felt to be of an elastic consistence. A diagnosis of an ovarian cyst or a fibroid of the uterus pressing on the bladder was made. There was no rise of temperature. A large quantity of urine was drawn off by catheter; it contained neither albumin nor sugar, but unfortunately it was not examined for the presence of organisms. The tumour still persisted after catheterisation. Laparotomy was performed and the uterus and ovaries were found to be normal, but displaced downwards and backwards by the tumour, which was of a darkred colour and covered by peritoneum, with many large vessels coursing over the surface. It was then seen to be connected to the upper wall of the bladder, and in view of the size (3 × 3 inches approximately) and of the hardness of the structure it was thought to be a new growth arising from the bladder; no attempt was made to remove it. Three days later the temperature rose in the evening to 103° F. and became hectic (normal to 103°) for several days. She then passed a considerable quantity of pus, accompanied by large flakes of lymph, in the urine. The tumour was found to have disappeared, but from time to time it re-formed and emptied itself, eventually disappearing entirely. From the urine a pure culture of B. coli was obtained. A year afterwards the patient was perfectly well, and nothing was to be felt either per hypogastrium or per vaginam. Turbid urine is still passed occasionally, the turbidity being due to B. coli, and no pus cells are to be found on these occa-Vaccination was adopted in the first instance, but has not been persevered with.

These three cases have all occurred in women, but the infection is not confined to them. A man, aged 30 years, was sent to me by Mr. F. Burghard with a history of recurrent attacks of fever and general malaise associated with pain in the region of the left kidney. At these times he has much pus in the urine, but in the intervals there are only B. coli and no pus cells. He is also improving, and the attacks are becoming less severe in intensity, but not in frequency under treatment by vaccines obtained from the organisms which he

The following case is not so clear, though suggestive. child, aged 9 months, was admitted under my care at the Evelina Hospital from Dr. H. C. C. Mann's out-patient department. She had been quite well up to three months before admission, when she developed an attack of bronchitis, with occasional discharge from the right ear. This discharge had been last noticed three days before admission, on which date there had been some sort of a fit, but a reliable account of it could not be obtained. In the interval several more fits occurred, and slight right-sided internal squint was present. vulsions. The parents had lost three children from con-The child had been correctly fed and there was nothing to suggest congenital syphilis. Nutrition was good. There was slight head retraction with marked irritability and general cutaneous hypersesthesia. Kernig's sign was

present and a questionable left internal squint. The kneejerk was obtained on the left side, but not on the right. There was also a perforation of the right membrana tympani. Lumbar puncture produced 16 cubic centimetres of clear fluid, containing no cells, and from which no growth was obtained from inoculation on to suitable media. The cerebral symptoms were relieved by this lumbar puncture. urine contained large quantities of B. coli and a few pus cells, and was very acid in reaction. Calmette's tuberculo-ophthalmic reaction was negative. The temperature ranged between 99° and 103° F., and the pulse from 140 to 150. No alteration in the condition occurred, and the child died on the eleventh day after admission. Post mortem nothing abnormal was found, and cultures from the spleen, heart blood, and kidney remained sterile. course of the case suggested an acute toxemia, and the only pathological condition detected was the presence of bacilliin the urine.

In treating one of these cases it is necessary to discriminate between the severe and milder types of case. Because the bacilli are found in the urine it is not necessary at once to rush to vaccines, and even in the more chronic-forms where vaccination will be the best remedy it is inexpedient to neglect all other measures and rely on thisalone. Many such cases must have occurred in the past when the condition was less well recognised and must have recovered, and no doubt many cases of unexplained febricula may have been instances of this condition. Therefore each case ought to be treated according to the severity and duration of the disease. The milder forms will yield to the well recognised treatment of an ordinary febrile attack, a hot bath, a mercurial purge, rest in bed, and reduced diet. Should the condition not clear up at the end of a week or ten days, then the sooner more radical measures are adopted the more likely is the condition to resolve. It should be remembered that the B. coli is an inhabitant of the intestine and in cases of constipation flourishes to a marked degree. Therefore it is important to promote a fairly free evacuation of the bowels daily. Without such an evacuation all other treatment will be unsatisfactory. In the second place it is well to give some intestinal antiseptic to hinder the growth of the organism, such as creasote or small doses of calomel (1/20th of a grain) after each meal. This latter drug in such doses has in my hands proved fairly satisfactory, but some prefer to try to replace the B. coli with a lactic acid bacillus by means of artificially soured milk. Seeing that many of the preparations of lactic acid organisms contain no living bacilli this is less certain than it appears. The B. coli flourishes in an acid medium; it is therefore advisable to alter the reaction of the urine, which should be rendered alkaline by the administration of the drugs usually employed to this end, to which urotropine in 5 or 10 grain doses may be added. This relieves the patient of many unpleasant symptoms and hinders the proliferation of the organism. The urine should be tested from time totime to see that enough alkali is being given, and it is sometimes advisable to give rather more than the usual dose the last thing at night. This will often be successful in procuring a good night's rest without the employment of anodynes.

Should this treatment not be successful in diminishing the numbers of the micro-organisms in the urine and relieving symptoms it is advisable that inoculation should at once be resorted to. It is undoubtedly best to employ a vaccine prepared from the organism which is attacking the patient, and a vaccine can easily be prepared in the course of three days. Inoculations should be given every seven or eight days. The initial dose for an adult of 50,000,000 of dead organisms (estimated according to the method advised by Sir Almroth Wright) will be comfortably tolerated. The second dose should be half as much again, and so on. It is also advisable to have a fresh vaccine prepared each month, better results being obtained than when the same vaccine is employed continuously. This may be explained on one or two grounds. Either the vaccine loses some of its potency or the organism is able to develop power to protect itself from the antibodies produced by the host as a result of the vaccination. It will be remembered that this latter occurs in the case of trypanosomes against which atoxyl is administered. Whichever explanation is correct, the fact remains that greater improvement takes place when the vaccine is freshly prepared every month.

It must always be remembered that the condition, when

once well established, is very refractory, and it is well to start treatment early and to carry it out energetically. The general health must also be seen to and any abnormality should be rectified.

Harley-street, W.

A CRITICAL REVIEW OF SOME CASES OF PERFORATION OF STOMACH AND DUODENAL ULCER.

BY JAMES GRANT ANDREW, M.B., C.M. GLASG.. F.F.P.S. GLASG.,

SURGEON TO THE VICTORIA INFIRMARY, GLASGOW.

It has been my lot within a period of nine months (from March to December, 1908) to deal with 13 cases of perforation of the stomach and duodenum. Some of the cases, indeed all of the cases, were interesting and instructive from some point of view, and I hope that the publication of the abbreviated history in each case will be helpful. For the abstract of the history, and for the trouble taken in working up the details of this paper, I am indebted to my former house surgeon, Dr. F. C. Macaulay.

The gastric cases are taken first, and though counted as 10 in number might be regarded as 12 perforations, for the first case was operated upon for perforation on three separate occasions. Though no perforation was discovered at the first operation, in view of the subsequent history (see Case 1) I think it more than probable that some leakage had occurred. The site of the ulcer on the second and on the third occasion was different. They were both situated, however, close to the pylorus, the second occasion on the anterior wall, and the third on the posterior wall. At the third operation no trace could be found of the previous ulcer on the anterior wall.

That it is possible to have an ulcer so eroding the coats of the stomach or bowel as to give rise to symptoms and signs suggestive of perforation, and yet on examination reveal no macroscopic evidence of leakage, I have no doubt whatever. In Case 9 the sudden and severe onset, accompanied by pro-nounced rigidity and tenderness of the epigastrium and followed by such profound collapse, certainly suggested leakage, and yet, though the ulcer was discovered and the serous coat was carefully examined, no actual hole was seen. I remember on another occasion examining with Dr. A. Johnston, then of Ruchill Fever Hospital, a case of suspected perforation in a man suffering from enteric fever. Neither of us had any doubt that a perforation had occurred, and though in several of the ulcers the dividing line seemed to be no thicker than tissue paper no visible point of leakage was discovered. In both of these cases there was some free fluid in the abdominal cavity, and the serous lining of the bowel was slightly injected. Is it possible that by osmosis an infection of the peritoneal cavity could be brought about, the serous coat over the site of the ulcer becoming, if not dead, so non-resistant as to act like a piece of soaked parchment? It is not infrequent to find in the previous history the record of an attack of pain severe enough to suggest leakage, and one has, unfortunately, known patients lulled into a sense of security by the belief that their present seizure of pain, though more severe, would pass off like the last and refuse operation until it was too late.

Ten of the cases were gastric and three duodenal.

Age and sex.—The ages ranged from 16 to 72 years. The average age over all was 37.7 years. The average age The average age of the gastric cases was 36.8 years, of the duodenal cases 41 years. Of the 10 gastric cases only 3 were in females whose average age was 19 years. The 3 duodenal cases were in men.

Onset.—In 12 out of the 13 cases the onset might be said to be instantaneous; in one (Case 12) the onset was more or less sub-acute. In the majority no food had been taken for some time previously, and the time of perforation was oftenest in the late hours of the evening or in the early Case 4 created a considerable amount of interest, owing to the fact that he was seized while dressing for his marriage. He collapsed, but rallied somewhat and went through the service, only, however, to be snatched from the arms of his bride and handed over to the care of the

young bride accepted the position with that stolid indifference and apparent want of feeling which is said to be so characteristically Scottish.

Previous history.—In eight (Cases 1, 3, 5, 7, 8, 9, 10, and 13) there was definite history of pain after food and other gastric symptoms; in the remaining five (Cases 2, 4, 6, 11, and 12) no history of previous gastric trouble was obtained. The occurrence of gastric symptoms previous to the onset is of considerable diagnostic value. Some of those who stated that they had had no previous stomach trouble admitted afterwards to having at times had feelings of discomfort which they had attributed to flatulence. But the point to note particularly is that a patient's statement as to the previous absence of stomach symptoms does not preclude the possibility of ulcer, nor does it preclude the possibility of the acute symptoms being those due to perforation (Case 12).

Pain.—It is almost considered a surgical axiom that in all cases of severe abdominal crises the pain is first of all referred to the epigastrium—solar plexus, and after some time to the particular seat of origin, to the appendix, to the gall-bladder, to the stomach. In every case of this series pain was a prominent feature, but was quite impossible to define except that it was severe, "doubled him up," "made him cry out," &c., and was equally difficult to locate apart from surface tenderness. The patients were so ill that speaking was an additional agony and as little as possible was said and indeed asked. In six cases, however, the pain was definitely referred to the epigastrium, in other three the pain began around the umbilicus, remaining there in one (Case 13, duodenal) and in the other two becoming epigastric later. In two the pain was felt in the shoulders as well as in the abdomen—both gastric—so that in 9 out of 13 cases the pain was referred to the upper part of the abdomen.

Vomiting subsequent to the onset was stated to have occurred in seven cases (Cases 1, 3, 4, 5, 6, 12, and 13). In three it was stated that no vomiting had occurred (Cases 2, 7, and 10). In three vomiting was a prominent symptom before the onset of the acute attack (Cases 1, 3, and 8). The vomit subsequent to the onset was "stomach contents"; in one case it was "coffee grounds."

Coilapse was a prominent feature in most of the cases, depending upon the length of time since the onset. It was definitely stated to be present in every case to begin with, but passed off gradually in some cases quicker than in others e.g., in Case 2 and in Case 8.

Appearance in most cases was indicative of severe pain; the patient looked very ill; the face was pale with malar flush.

Flatus per rectum.—The length of time subsequent to perforation was so short comparatively that the non-passage of flatus was less important as indicating peristaltic paresis. In two cases flatus was definitely stated not to have passed since onset.

Respiration. —The earlier the case was seen the more likely was the breathing found to be thoracic in type and the more averse the patient was to take a deep inspiration. In five cases the respirations were stated to be wholly thoracic; in three the abdomen was said to have moved slightly; in the others no reference was made to the character of the respirations.

The temperature varied from 97° to 100.8° F. The temperature depended upon the length of time that had elapsed since the perforation.

The pulse varied from 70 to 138 per minute, also evidently dependent upon the length of time since the onset. A gradually increasing pulse-rate is significant.

Abdomen. - Distension was definitely present in four cases (Cases 6, 8, 10, and 13); the longer the time the greater the distension.

Rigidity of the abdominal wall.—This is a sign of much aportance. With one exception (Case 10) it was present in importance. With one exception (Case 10) it was present in every case. In 11 of the cases the rigidity was general, in two it was epigastric, but in every case it was more evident over the stomach. In one case (Case 12) the main rigidity was found on the right side; in another the contraction of the recti was visible (Case 7). The earlier the case the greater was the rigidity. In the only case where it was stated to be absent nearly 60 hours had elapsed from the time of onset

and the general peritoneal cavity was found to be shut off.

Tenderness, abdominal, on palpation was present in every surgeon. In the by-going it might be mentioned that the case with one exception (Case 2) and in that case there had been tenderness which had passed off, and as this case was seen within a few hours from perforation the tenderness from peritonitis had not had time to manifest itself; the ulcer, moreover, was on the posterior wall. In six cases there was epigastric tenderness only; in the remaining seven it was general, with perhaps a greater degree of tenderness in the epigastrium.

Liver dulness.—In ten cases there was some alteration in the liver dulness; in three cases the liver dulness was completely gone (Cases 3, 11, and 1), in seven cases it was encroached upon (Cases 2, 4, 5, 6, 7, 8, and 13) and in three cases the liver dulness was normal (Cases 9, 10, and 12). No actual perforation was found in Case 9; in Cases 10 and 12 the general cavity was not at first affected. In this connexion it is interesting to note that the liver dulness will be found encroached upon after every abdominal section, more especially if it involve the upper area of the abdomen. As the air gets absorbed the normal limits of dulness return. The length of time varies from a few days to a fortnight.

Signs of free fluid in the abdominal cavity were obtained in six cases; in the others these signs were absent or uncertain.

The length of time between the onset and operation varied from 4½ to 80 hours. Seven cases (Nos. 1, 2, 4, 5, 7, 8, and 9) were operated upon under 12 hours; of these 2 died-Cases 7 and 8 (Case 8 was complicated by cirrhosis)

Operation. —In every case to begin with a small vertical incision about one inch in length was made in the suprapubic region. This enables the surgeon at once to ascertain whether there be free fluid in the abdominal cavity and its nature, and the condition of the serous coat of the bowelwhether it be injected or not; it can also be used for subsequent drainage. The amount of free fluid in the abdominal cavity varied; at times it simply welled out, at others the quantity was so small as to be practically non-existent. fluid in appearance suggested dish-water, turbid, with flakes of lymph if the perforation had existed for over six to eight hours and usually odourless. In no case were there solid particles of partly digested food; in one case the fluid had a distinctly alcoholic odour, the patient having taken a glass of brandy subsequent to the perforation. Gas was present, free in the abdominal cavity, in the majority of the cases, accounting for the absence of liver dulness.

Seat of perforation. - The stomach was exposed by a vertical incision made slightly to the left of the middle line. In eight instances the perforation involved the anterior wall of the stomach; in six of these it was towards the lesser curvature and close to the pylorus. In two the posterior wall was the seat: in one of these about its centre, and in the other at the pylorus. In the three duodenal cases the ulcer was situated in the anterior wall of the first part, so that it might be said that in 11 out of 13 cases the ulcer was situated in the immediate neighbourhood of the pylorus.

The size of the perforation varied from that of a pin's head to that of an opening as large as a threepenny-piece. As already stated, no visible perforation was discovered in Case 1 -first operation—or in Case 9.

Closure of the perforation. - In no case was any attempt made to excise the ulcer or to do more than simple closure. This was effected either by a double row of catgut or an outer row of silk and an inner of catgut. In three cases the amount of induration round the ulcer was so extensive and the tissue so friable that the inturning was a matter of some difficulty. A strand of iodoform gauze was led in two of these cases from the abdominal wound to the seat of the perforation as an additional security. I do not, however, consider this a wise procedure, as protective adhesions so soon form and a via media is left for infection.

Flushing the abdominal cavity was in every case carried out with warm saline with drainage from one or both flanks as well as by the suprapubic opening. The abdominal wound was closed by through-and-through silkworm gut stitches.

After-treatment. - In every case the upper end of the bed was placed upon high blocks—Fowler's position—as soon as the shock had passed off. Saline solution was given fourhourly per rectum, and strychnine, either with or without digitalin, was given hypodermically if the pulse demanded it. Nothing was given by the mouth before the end of the third day, the patient being nourished by nutrients administered per rectum, consisting of peptonised milk (4 ounces), saline solution (2 ounces), with brandy if A wash-out enema was given every day. Turpentine enemata combined with the frequent passage of

the flatus tube were of great value in flatulent distension. The glass drainage tube draining the pouch of Douglas was removed on the second day, never later than that; the omentum is apt to find its way into the tube, and if left longer the continuous pressure on the already devitalised bowel has been known to lead to ulceration and the establishment of a fæcal fistula. Oral feeding consisted at first of water in small quantities soon followed by dilute peptonised milk. At the end of seven days farinaceous foods were given; then in another week light diets, fish and chicken, cream, &c.

Complications. - Wounds all healed primarily save in Case 5. where some suppuration formed round a stitch hole. Parotitis followed in two cases (Cases 5 and 9). Case 5 went on to suppuration; Case 9 subsided under lead and opium lotion. Hæmorrhage persisted from the wounds and from the stomach in Case 8 for some days-attributed to the cirrhotic condition of the liver.

Mortality.—If the gastric cases be taken alone (10 cases) 6 recovered, 60 per cent.; and 4 died, 40 per cent. The three cases of duodenal ulcer died, in each case within 24 hours from operation. In Case 12 the ulcer was only discovered post mortem, it was not found at the operation.

PERFORATION OF GASTRIC ULCER.

overed post mortem, it was not found at the operation.

after perforation. A suprapuble incision was followed by the escape of milky fluid. The bowel was congested and on searching for the appendix it was found normal. Incision was then made over the stomach; fluid and gas escaped. A perforation, an eighth of an inch across, was found on the anterior wall close to the pylorus. This was closed with catgut and silk. A drainage-tube was then inserted in the right flank and the abdominal contents were washed with warm saline solution. The abdomen was closed with through-and-through salmon-gut sutures, a glass drain being left in the suprapuble wound. After-treatment: Fowler's position was adopted. The patient was given saline solution per rectum and strychnine every four hours. Nutrient enemata were administered. The glass tube was removed on the 21st; the pulse then was 92 per minute and the temperature was 99? The bowels were moved on the 22nd. Thence the patient made steady progress till he left on June 24th.

CASE 4.—A man, aged 26 years, was admitted on Sept. 23rd, 1908, at

bowels were moved on the 22nd. Thence the patient made steady progress till he left on June 24th.

CASE 4.—A man, aged 26 years, was admitted on Sept. 23rd, 1908, at 1.50 A.M. At 7 P.M. on the 22nd, while dressing for his marriage, he was selzed with sudden pain in the abdomen which was sufficiently severe to make him cry out. The pain was referred to 1 inch above the umbilicus in the middle line. He vomited stomach contents and became quite collapsed. The pain then subsided a little and he went through with the marriage ceremony. Thereafter the pain became worse and was general all over the abdomen, vomiting occurring several times. His bowels, which had always been regular, were moved on the day of onset of illness. No previous stomach history was obtained. Dr. W. K. Peden was called to see him, recognised the condition as one of perforation, and sent him at once to the infirmary. On admission the patient was in great pain and was very restless, tossing about but keeping his legs drawn up. The face was pallid with malar flush; the tongue was furred but moist. The abdomen moved slightly with respiration and was not distended. Both recti stood out visibly and on palpation general rigidity was pronounced. There was also general tenderness, very acute 1 inch above and slightly to the right of the umbilicus. Percussion was clear in front but dull in both flanks. The liver dulness (nipple line) was 3 inches. The pulse was 104 and the temperature was 99:20 F.

Operation was performed by Mr. Grant Andrew 64 hours after the conset. A suprapulce incision was followed by escape of vellow weters.

temperature was 99.2° F.

Operation was performed by Mr. Grant Andrew 6½ hours after the onset. A suprapuble incision was followed by escape of yellow watery fluid with lymph flakes. On opening in the epigastrium fluid and stomach contents escaped. A pinhole perforation was found on the anterior wall, lesser curvature, quite close to the pylorus. This was closed by a double Lembert suture of catgut and silk. The abdomen was then irrigated as usual with drainage through the right flank in addition to the wounds in front, and the abdomen was closed with through and through salmon gut. After-treatment: Fowler's position was adopted. Saline solution per rectum and nutrient enemata were given. On the 24th both tubes were removed and water was given by the mouth. On the 25th both pulse and temperature rose, but were normal the next day on the discontinuance of the fluid by the mouth. The bowels were moved on the 27th. Nutrients were stopped entirely on Oct. 5th, and the patient left well on the 28th. Since then he has been back looking well.

CASE 5.—A male, aged 51 years, was admitted at 11.45 P.M. on Sept. 23rd, 1908. At 4 P.M. that day he felt sudden acute pain in the epigastrium and became prostrated. Vomiting occurred several times, and as his symptoms did not lessen in severity a medical man was called in who ordered his removal to hospital. There was a definite history of gastric ulcer for three years with aggravated symptoms for two months. On admission the patient looked very ill and was evidently suffering greatly. The tongue was dry and furred. The abdomen was very rigid and generally tender, both signs being most notable above and to the left of the umbilicus. The liver dulness was 2 inches in the nipple line. Signs of free fluid were obtained. The pulse was 90 and the temperature was 99.6° free fluid were obtained. The pulse was 90 and the temperature was 99.6° free fluid were obtained. The pulse was 90 and the temperature was 99.6° free fluid were obtained. Operation was performed by Mr. Grant Andrew 64 hours after the

was 99.6° F.

Operation was performed 9½ hours after perforation. The usual incisions showed typical fluid in the abdomen. The perforation was in the anterior wall, lesser curvature, and near the cardiac end; there was marked induration all round it. It was repaired by continuous catgut and silk stitches. Saline irrigation and drainage were carried out as usual. After-treatment: Fowler's position was adopted. Saline solution and nutrients were given per rectum every four hours. The drainage-tubes were removed on the 26th and the patient did very well until Oct. 4th, when parotitis of the right side developed with rise of the pulse and temperature. He left well on Dec. 12th, and since discharge has been back looking in good health.

CASE 6.—A female, aged 19 years, was admitted on Oct. 31st, 1908. 12 hours before admission she was selzed with sudden agonising abdominal pain, at first round the umbilicus, in the back, and both shoulders, and later over the stomach. She vomited stomach contents and was completely collapsed. Improvement shortly took place and

minal pain, at first round the umbilicus, in the back, and both shoulders, and later over the stomach. She vomited stomach contents and was completely collapsed. Improvement shortly took place and she felt more comfortable till six hours later, when the pain became aggravated, being felt generally all over the abdomen. She again vomited several times, the vomit being gastric contents. On admission the face was pallid; the tongue was clean and moist. The temperature was 94°F and the pulse was 138 and full in volume. The respirations were wholly thoracic. There was great distension of the abdomen. Percussion revealed the presence of fluid free in the general abdominal cavity. The liver dulness in the nipple line was two inches. Rigidity, while general, was extreme over the stomach, the same applying to tenderness, which was agonising at a spot midway between the xiphoid and the umbilicus. There was a history of gastric ulcer, which had, however, ceased to trouble her two and a half years before.

Operation was performed by Mr. Grant Andrew 13 hours after the onset. The abdomen was opened above the pubes by a small incision and was found full of fluid, which gushed out; it contained large lymph flakes and mucoid matter. The epigastric incision was followed by a rush of gas and fluid. A small, cleanly punched-out perforation was found in the anterior wall, near the cardiac end; this was closed by a double Lembert's suture of catgut and silk. Then followed flushing with warm saline solution and drainage in the flank and in front. After-treatment: Fowler's position was adopted when shock had passed off. Saline solution per rectum (one pint) and had an ounce of brandy were given every four hours. Strychnine and digitalin were given every four hours and the patient received nutrients. On Nov. 1st she was very restless. The pulse was 163 and the temperature was 103.2°. Flatus was passed. On the 2nd the glass tube was removed from the suprapuble wound. The pulse was 163 and the temperature was 103.2°. That was passed. On

7.30 A.M. on Nov. 3rd. This case was sent in by Dr. William Lawson with

7.30 a.m. on Nov. 3rd. This case was sent in by Dr. William Lawson with the diagnosis of peritonitis, due probably to perforated gastric ulcer.

Case 7.—A male, aged 46 years, was admitted on Nov. 18th, 1908, at 11 a.m. While at work two hours before he was seized with agonising pain situated at first round the umbilicus, and later in the epigastrium and over the stomach; he became quite collapsed. Vomiting did not occur then or subsequently. After sitting outside for two hours he was brought along to the hospital. There was a history of pain and coffee-ground vomiting for a long time back. On admission the patient looked very ill, with pallid face and cold clammy skin. The pulse was 70 per minute and very weak; the temperature was 97.6° F. He abdomen was not distended, and it moved with respiration. Both recti were visibly contracted. Rigidity was present all over, being extreme in the epigastrium. There was slight epigastric tenderness, but no general tenderness. Percussion was clear in front and dull in the flank—rice-versi when the patient lay on his side, the note in the upper flank—theing resonant then. The liver dulness was encroached upon as regards its lower border by two inches. It was also noticed that the man lay with his legs drawn up.

heing resonant then. The liver dulness was encroached upon as regards its lower border by two inches. It was also noticed that the man lay with his legs drawn up.

Operation was performed by Mr. Grant Andrew six hours after perforation. The usual suprapuble incision revealed yellowish watery fluid with large lymph flakes in it. On incising the epigastrium a large perforation was found on the anterior wall, lesser curvature, near the pylorus. Induration extended for fully half an inch all round its circumference. It was closed as usual, a much larger portion of the stomach wall requiring to be invaginated to obviate the indurated base. The abdomen was then irrigated with a rubber drain in the flank. The operation was completed as usual save for the introduction of a strand of iodoform gauze, which was packed down to the site of the perforation in case there might be further leakage. Drainage was provided for by two tubes, glass and rubber. The fluid found in the abdomen had a distinctly alcoholic odour, the patient having taken a glass of brandy after the pain began. After treatment: Fowler's position was adopted. The patient was given nutrient enemats of peptonised milk (4 ounces), saline solution (2 ounces), and brandy (5 ounce). On the 19th his pulse was 100 and the evening temperature was 1016°. Flatus was passed by the rectal tube. On the 20th the glass tube was removed. The patient was much the same. On the 22nd the bowels were moved in bed, so nutrients were stopped. The gauze was removed from the epigastric incision. On the 23rd the pulse was 84. Milk and water were given by the mouth; there was no pain, tenderness, or distension. On the 30th the pulse was 16; the patient looked very ill. The abdomen showed of peritonities or of localised collection. The temperature was 99°. On Dec. 1st he gradually sank and died at 3 P.M. No necropsy was allowed.

Case & A. Male, aged 43 years, was admitted on Dec. 26th, 1908, at

no sign of peritonitis or of localised collection. The temperature was 399. On Dec. 1st he gradually sank and died at 3 r.m. No necropsy was allowed.

Case 8.—A male, aged 43 years, was admitted on Dec. 26th, 1908, at 3 A.M. The night before, at 11 r.M., he complained of sudden excruciating pain in the abdomen and became collapsed. Dr. D. Lamb, who was called in, sent him into the infirmary at once. Four years before he had acute pain and coffee-ground vomiting after food. These symptoms had abated, but returned a month before admission. There was also a history of immoderate indulgence in alcohol. On admission the patient was very drowsy and insisted upon going to sleep. He had no pain and lay comfortably on his right side with his legs drawn up. The breathing was thoracic. The abdomen was moderately distended and, while very rigid all over, was specially so in the epigastrium. Tenderness was ac: te over the stomach, more so to the right of the middle line. The u ual signs of free fluid were present, and the liver dulness was encroac; ed upon, measuring two and a half inches in the nipple line. The pul e was 96 and the temperature was 97.6° F.

Operation was performed by Mr. Grant Andrew at 4 A.M., five hours after perforation. On opening the abdomen above the pubes the turbid fluid typical of perforated gastric ulcer was found. The usual epigastric incision was made, and oy drawing out the stomach a tiny perforation was found almost on the pylorus, anterior wall. The liver was found to be extremely hobnailed. The perforation was closed as usual, and after making a drainage wound in the right flank the abdomen was irrigated with warm saline solution. Drainage was provided for by glass- and rubber-tubes in the hypogastrium and flank respectively. Iodoform gauze was also packed down to the site of the ulcer. After-treatment: Fowler's position was adopted. The patient was given saline solution per rectum alternately with nutrient enemata four-hourly. On the 26th the pulse from 96 ran up to 130 in the evening. The

died.

CASE 9.—A female, aged 22 years, was admitted on Dec. 27th, 1908, at 2 A.M. The night before, at 11 P.M., extremely severe pain developed over the stomach. The pulse was feeble and almost imperceptible. There was great rigidity of the epigastrium and excessive tenderness there. She seemed so ill that perforation was suspected. Mr. Grant Andrew, who saw the case in consultation with Dr. Hugh Kelly, considered the case sufficiently urgent for exploratory laparotomy. The pulse was 90 and the temperature was 97° F.

Operation: The suprapuble incision was negative. The anterior wall of the stomach when examined through an epigastric incision was

Operation: The suprapuble incision was negative. The anterior wall of the stomach when examined through an epigastric incision was found normal. The posterior wall was then examined and an ulcer was found at the pylorus. The base of the ulcer was much thinned down, consisting practically of the serous coat. There did not seem to be any actual perforation. The abdomen was closed with through-and-through salmon gut. After-treatment: The patient was given nutrients of peptonised milk and saline solution for the first week, during which there was no oral feeding. During the second week dilute peptonised milk was given by the stomach. With the exception of a parotitis which subsided without suppuration convalescence was entirely satisfactory and the patient left well on Jan. 26th with symptoms of several months' duration quite gone.

CASE 10.—A male, aged 72 years, was seen in private with Dr. H. C. Leask at 9 p.M. on Jan. 20th, 1909. On Monday, the 18th, while at business, the patient was seized with sudden severe abdominal pain and had to go home in a cab, even although his house was quite near. There

The pain gradually became less, but did not entirely go away. Hiccough also became troublesome. The bowels had not been moved for two days before the onset nor had they been moved up to the time of the consultation on the 20th. No flatus had been passed for two days. The abdomen was moderately distended and was not rigid. There was a little tenderness in the epigastrium, but none elsewhere. The liver dulness was normal and there was no dulness in the flanks. The case was regarded as one of malignant disease of the large bowle, probably at the splenic flexure. On the next day, Jan. 21st, it was reported that flatus had been passed during the night and that the natient was at any rate on worse.

reported that flatus had been passed during the night and that the patient was at any rate no worse.

Operation was performed by Mr. Grant Andrew at a nursing home. The abdomen was opened by a suprapuble incision and free fluid was found, but with no special characteristics. On pulling down the transverse colon stomach contents were observed evidently in part shu off from the general cavity. A perforation was found in the anterior wall of the stomach about two inches from the pylorus, with omentum adherent around it and almost closing it. The serous coat of the stomach was stained black all round the ulcer, the result of administration of bismuth for dyspepsia of many years' standing. The amount of induration in the immediate neighbourhood of the perforation rendered it difficult to close. Though the probability was that the ulcer was malignant there was no positive evidence of that fact. The opening was closed and drainage was established in the flank and pelvis. The patient had a good night after the operation, and his loweds.

PERFORATION OF DUDDENAL LUCER

PERFORATION OF DUODENAL ULCER.

ition. No examination was allowed.

Perforation of Duodenal Ulcer.

Case II.—A male, aged 43 years, was admitted at 2.30 a.m. on March 7th, 1903, as a case of appendicitis. On Friday, the 6th, at 9 a.m. he felt very acute pain in the abdomen, which quite doubled him up. No further history was obtained. On admission the patient looked extremely ill, with short hurried respirations, 50 per minute, entirely thoracic. Rigidity and tenderness were both generalised over the abdomen, but were most marked on the right side. The percussion note was tympanic. The liver dulness had disappeared. The temperature was 99.20 F. and the pulse was 120.

Operation was performed by Mr. Grant Andrew 243 hours after perforation. A suprapubic incision allowed purulent matter to escape. The appendix was identified and found normal. Gas escaped freely when an incision was made in the epigastrium. A perforation was fushed with warm saline solution and drained. After-treatment: Fowler's position was adopted. Nutrients were given per rectum, strychnine, &c. The pulse gradually got worse, rising from 126 to 150, and the patient died at 6 P.M. the same day.

Case 12.—A male, aged 26 years, was admitted on Oct. 31st, 1908, as a case of appendicitis. The history was that of having felt unwell for eight days without definite symptoms beyond headache and constipation. On Thursday, the 29th, he felt slight epigastric pain and also vomited, a symptom which had not recurred up to admission. There was no history of dyspeptic symptoms. On admission the face was pallid with malar flush and sweating freely. The abdomen was not distended and moved with respiration. Tenderness was marked in the epigastrium and right lilac fossa, and rigidity was personal all along the right rectus and also in the epigastrium. The re in where pain was most complained of was in the right iliac area. Over the appendix there were relative dulness, fulness, and gurglin are was 93.40. The leucocytes numbered 6700 per cubic millimete. On the next day the pulse was 34 per minut

At the post-mortem examination hemorrhagic areas were found in the small bowel, but with no ulceration in these parts. On the first part of the duodenum there was a large chronic ulcer with a minute perforation in the centre through which leakage had occurred. Round the perforation there were adhesions of a soit nature and a large effusion of lumnh

perforation in the centre through which leakage had occurred. Round the perforation there were adhesions of a soft nature and a large effusion of lymph.

Case 13.—A male, aged 54 years, was admitted at 10 p.m. on Nov. 4th, 1908. The history showed that at 6 o'clock on the previous evening he was seized with very severe pain. This began around the umbilicus where it remained constant; in consequence he became quite collapsed. His bowels were moved on the morning of the 3rd, but not since, nor was fistus passed subsequent to the onset of the pain. He vomited once, the vomit being merely gastric contents. He received treatment at home for intestinal obstruction. As regards the previous history, for some years he had had slight pain after food, not occurring after every meal but felt now and again at long intervals. On admission the patient looked very ill, with pallid face. His tongue was covered with a thick, white fur. The position he voluntarily adopted was that of dorsal decubitus, with the legs drawn up. The temperature was 100.85 f. and the pulse was 106. The respirations were entirely thoracic. There was considerable fulness of the abdomen, uniformly distributed. General rigidity was present, most evident in the epigastrium, where it was of stony hardness. Tenderness also was a well-marked feature, being clicited all over the abdomen and in particular one and a half inches above and to the right of the umbilicus. It was more severe all over the right of the umbilicus. It was more severe all over the right side than on the left. On percussion a clear note was obtained in front, and dulness in both flanks. When the patient lay on his side, however, the uppermost flank did not become clear. One inch of liver dulness remained.

Operation was performed by Mr. Grant Andrew at 11 p.m., 29 hours after the onset. A surranulci neiging of one inch was fallowed the after the onset.

of liver dulness remained.

Operation was performed by Mr. Grant Andrew at 11 P.M., 29 hours after the onset. A suprapuble incision of one inch was followed by a rush of gas and fluid of a turbid and yellowish nature. The source of the fluid was found to be a perforation, about the size of a threepenny piece, in the anterior wall of the first part of the duodenum. This was closed by a double Lembert suture, the first layer of catgut and the second of silk, and a piece of omentum also was tacked down over it. The abdomen was flushed with warm saline solution, drainage being

established through both flanks and a glass tube in the suprapuble wound. After treatment:—Fowler's position was adopted. The patient received saline solution per rectum, strychnine, four hourly, &c. He grew rapidly weaker and died 52 hours after the operation. Glasgow.

THE SELECTION OF PATIENTS FOR SPA TREATMENT.1

BY NEVILLE WOOD, M.D. DURH., M.R.C.P. LOND.

As in the time allotted I have in more senses than one a great deal of ground to cover I will dispense with prefatory remarks and plunge at once in medias res. There is apt to be a certain evasiveness about balneological literature—a vice which is only to be avoided by bringing the fundamental facts into close apposition. Let me, then, ask your attention to a series of propositions, which, moreover, will save much repetition later on. 1. The principal aim of spa treatment is the furtherance of metabolism and the promotion of excretion. 2. The treatment, consisting as it does of the specialised use of what are known as natural remedies, is to be considered in relation to patients who cannot or will not employ those means at home, or who for some reason are not amenable to drug treatment. 3. Though spa treatment is often merely an alternative for other methods, it is pre-eminently suitable for cases on which it is desirable to concentrate a number of differing influences. 4. Spas may be used for prophylaxis, but climatic stations are to be preferred for convalescence. 5. Whenever there is a suspicion of visceral disease, a re-examination of the patient should be made immediately before his departure. 6. The best results from balneotherapy are obtained in the middle-aged and in young adults, while children and old people are more benefited by climatic influences. 7. Only by the most careful application of general principles can patients be properly selected for spa treatment; for though it has contributed much to the art of healing it has not added a single specific to the science of medicine. 8. The maxim "Non our atur qui our at" applies with especial force to those who are sent away from home. Full benefit can only be expected when the patient can leave business and domestic worries behind, and can face with equanimity the cost of the treatment and of the amenities of spa life.

Bearing these propositions in mind, let us pass in review the resources available and the manner in which they are turned to account, beginning with atmospheric influence

At all spas it is considered of primary importance that the climatic conditions should permit of the enjoyment of abundance of fresh air. As if by a providential arrangement, mineral springs are usually found at a moderate altitude, in valleys clad on their slopes with sheltering trees, and shielded from the colder winds by the disposition of their neighbouring mountains. Where natural shelter is insufficient art steps in, supplying it by the construction of embankments, the erection of shelters, and by plantations of trees. A special advantage of such carefully planned shelter, in these resorts, is that patients may return to the open air comparatively soon after taking even a very hot bath.

Next, with regard to exercise, at most continental health resorts many miles of splendid walks have been laid out Directions, distances, and gradients are so plainly indicated that regulated walking exercise is easily planned and carried out. While to meet the needs of those who will not exert themselves, except, so to speak, under the eye of a ganger, there are nearly always Zander gymnastic institutes, where every muscle can be brought into play, while in addition, manually given movements are available for those who may require them. In any case the custom of promenading while drinking the waters induces the patient almost unconsciously to take walking exercise to a fair extent.

Diet at the spas is a ticklish subject to handle, and in print we find it treated with a reserve which, though prudent, is uninforming. In former days the diet was governed by the name of the disease, or was influenced by the supposition that some of the articles of every-day consumption would clash with the action of the mineral waters. Physicians handed to the patient a stereotyped diet-sheet, and adherence to its restrictions was demanded. These

¹ Abstract of the Presidential Address read before the West London Medico-Chirurgical Society on Oct. 8th, 1909.

printed lists are now seldom seen, and it is the fashion to say that the diet is ordered according to the constitution of each individual. In practice, however, what often happens is this. The forbidden and the permitted articles are written out in parallel columns, but when any of those allowed are distasteful to the patient, or any of those banned are more acceptable to him, an interchange of the items is effected. Now, used with discretion, that is by no means a bad way of arriving at a suitable diet for some patients. But when rigid restriction is necessary the attempt to control hotel cookery is often a signal failure, and the medical man can seldom count upon knowing the exact composition of his patient's repasts. It is true that at Homburg and some other spas commendable attempts have been made to solve this difficult problem of hotel cookery for invalids. Nevertheless, my present information leads me to believe that a patient sent away from home for a cure dependent chiefly on diet should be placed in a sanatorium, where the kitchen is under the direct supervision of a medical expert, and where whatever is ingested is controlled in accordance with the results of a scientific investigation both of the secretions and the excretions.

The next, and of course in many instances the principal resource, is the bath. Of chief importance in balneotherapy is the thermal factor. Next to that perhaps comes the dynamic factor-that is, the influence of water in motion. This is brought to bear in several different ways. At Plombières, by means of the "douche Bottentuit," a jet of water from a submerged pipe with a special nozzle plays upon the abdomen while the patient lies in the bath. At Mont Dore the bather stands or sits while a stream of very hot water falls upon him from above. At Aix-les-Bains the douche is projected from a short distance, massage being given at the same time. At Vichy the water falls on the recumbent patient from perforated roses as from a series of watering pots.

The mineralisation of a bath is of importance quantitively rather than qualitatively. By this I mean that the action of the dissolved salts depends chiefly on their concentration. The mineral elements act by conveying a stimulus to the cutaneous nerves primarily and through them to the general nervous system. They also render the skin hygroscopic, and thus modify its evaporative function.

I will pass now to the uses of mineral water taken internally. Some springs are so richly mineralised that an ordinary glass—9 ounces—represents a tangible pharmacentical dose of their salts. Hence their primary action requires no explanation. Such springs are the Choussy Perrière of La Bourboule, the alkaline springs of Vichy, and the Marienbad Kreuzbrunnen. Many, perhaps the majority of cases, in which arsenic, sodium bicarbonate, and sulphate are indicated, can be treated just as well at home by these agents given in the conventional 6-ounce mixture. are instances, however, in which the natural water answers better than the pharmaceutical product, a fact of which we are impelled to seek for an explanation. Some impute the difference partly to the imagination and partly to the change in the patient's whole manner of life; others, among whom are of course the spa practitioners, assume that the products of Nature's laboratory are always superior to those of the chemist, that minimal quantities of other salts contained in these waters are important adjuvants, or that there exist in them unknown elements of high therapeutic potency. These last suggestions are not to be dismissed with contempt. There exist springs of extremely feeble mineralisation containing only salts considered pharmacologically inert, yet the waters of which have been drunk by thousands of patients for hundreds of years and still maintain their popularity.

I now come to cases in which elimination by the kidneys is indicated. In these we find that pharmacy supplies us with a great variety of agents which may successfully compete with the products of the springs. In deciding, therefore, whether or not to send patients to them, we have to consider the general and the specific resources of the spas, while laying more stress on the former. Vichy and Neuenahr are the chief spas at which elimination by the renal route is promoted by the use of the alkaline waters to be found there. Vichy has a splendid bathing establishment, the best in France, and the only one fully equal to the corresponding institutions in Germany, but I must add with regret that it is one of the most badly kept French inland watering places. English patients, once a numerous contingent, have dwindled in number, but as the loss so sustained is made up by visitors from southern countries the stimulus to amendment is lacking. Neuenahr does not as yet attract many British invalids, so that those who go there will find it rather dull unless they have some familiarity with the German language. Curiously enough, Neuenahr is rather untidy-a rare exception among German spas.

Recently, waters of a different type have been advocated for renal elimination. The features they have in common are, besides the presence of lime, the small percentage of dissolved salts, which in some instances amount to less than 0: 5 part per mille. A special point is made of their poverty in chlorides, a quality of great importance for those who lay stress on Widal's chloride deprivation theory. The stronger of these waters are found at Vittel, Contrexéville, and Wildungen; the weaker at Evian and Aix-les-Bains.

For centuries cystitis has been treated by the stronger waters of the earthy group as well as by those of the alkaline type, but probably in the future both sets of waters will be used merely as adjuvants since Sir Almroth Wright has shown us how to deal with the causative bacterial infections.

The slighter cases of nephritis are claimed by the renal spas just referred to, while there is a spring at St. Nectaire which is said to be specially beneficial when there is an associated phosphaturia. It need scarcely be said that in nephritis a suitable régime is of greater service than the use of any mineral water, and hence no very lasting benefit is to be expected from a sojourn at these spas; but if you desire to send a patient for a holiday to a place where his condition will be understood it is well to bear them in mind.

The spas whose speciality is elimination by the bowel are those with waters containing sodium sulphate, as Marienbad, Karlsbad, Brides-les-Bains, and Cheltenham. It is, of course, claimed that the fresh natural salt is more powerful in its action than the artificial pharmaceutical preparation. I have not been able to satisfy myself that this is the case, and I believe that if merely an aperient action is desired there is no special advantage in these waters. If, however, we look a little further ahead, to the restoration of the normal functions of the bowel, they are of the greatest possible value. The simplest explanation seems to be that they act, so to speak, as bowel lotions, and that they contain something which as it passes along the intestinal tract has a more beneficial influence locally than any corresponding pharmaceutical preparation. A curious point in connexion with sulphate waters is that in Germany and Austria it is believed that the cold waters have a much stronger aperient action than the hot, and that the function of the hot Karlsbad water is rather the treatment of diarrhoea. This is of practical importance, for if you happen to send to some of the Karlsbad physicians a patient suffering from constipation he is not unlikely to be told that the selection has been faulty and sent on to Marienbad, where the waters are cold. Brides-les-Bains is very much smaller than either of these places, much quieter, and less expensive. The waters are not very strong, and are so held suitable for cases not requiring drastic treatment.

Cheltenham deserves better appreciation than it receives. For many Anglo-Indians requiring eliminatory treatment it is superior to Karlsbad in all but prestige and hotel accom-The climate is mild and well suited all the year modation. round for those who have lived in the tropics, while, if the patient requires bracing, a short tram ride takes him to a hill where the air, though soft, is invigorating. In addition to the sulphate spring there is an alkaline water akin to that of Vichy. Cheltenham has, in being available at all seasons, an important advantage over its continental competitors, which are at their best only in the early part of the

It is universally admitted that the arthritic group of diseases—gout, rheumatism, and rheumatoid arthritis—are typically suitable for balneotherapy. These affections are placed in the list of indications by almost every wateringplace in Europe, but the only sound method of selection is to regard, not the name of the disease, but the associated constitutional condition, which must be essentially one of disordered metabolism, generally coupled with defective elimination.

At Aix-les-Bains local treatment by baths and massage has been brought to greater perfection than elsewhere, and the heat of this place, lasting well on into the evening, is of much

advantage to patients taking frequent baths at high temperatures. For the same reason the mild climate of Bath makes it the best spa in England for the more delicate arthritics. Moderately robust invalids may suitably be sent to Droitwich for treatment by the strong brine found there, or to Harrogate, where there is a considerable variety of waters. The waters of Buxton are so feebly mineralised that it is difficult to explain the good results obtained there. Woodhall Spa may be described as a quiet place for quiet people or a sleepy place for sleepless people, but do not send patients to whom the brightness of continental spas appeals to Woodhall unless you are prepared to have them upbraid you for dooming them to a foretaste of the Buddhist Nirvana.

Perhaps one of the most interesting problems in practical balneology is that of the value of the treatment of heart weakness by salt and carbonated baths, initiated by the late Professor Benecke of Nauheim. Its adequate discussion, however, would require more time than is now at my disposal. When good results are obtained I believe they are to be ascribed chiefly to an improvement in general metabolism in which the cardio-vascular system shares. It is an error to suppose that "Nauheim treatment" and treatment at Nauheim are convertible terms. Physicians there do not consider themselves restricted to the employment of baths and scheduled exercises. They treat the patient, in fact, according to his condition, whether this implies simply inspiring him with hope and arranging for the supply of plenty of fresh air with suitable diet, keeping him in bed and administering drugs of the digitalis group, or the use in combination of modern physico-chemical methods.

The spa treatment of syphilis was for many years almost a monopoly of Aix-la-Chapelle. Now Aix-trained rubbers are to be found in London and other large cities, while at many spas Aix methods have been successfully copied. In Germany the chief alternative spa is Wiesbaden and in France Uriage. Aix-la-Chapelle is a large town. It has luxuriously equipped baths, but otherwise has no special attraction. The disadvantage in sending a patient there is that he is thereby practically labelled as suffering from a loathsome disease. This is well recognised at Aix, and strenuous attempts are made to attract arthritic and other patients for whom sulphur water is commonly prescribed, but as over 60 per cent. of all the patients and over 80 per cent. of the English patients who go there are the subjects of specific disease the stigma, whether deserved or not, is not an easy one to efface.

The conditions of life at Uriage are such as to render it an ideal place for the treatment of syphilis. The composition of the water is exactly that which theoretically is required, and, what is more important, the results obtained are excellent. It has been shown that in syphilis the body suffers a considerable loss in iron, in lime and soda salts, and a still greater loss in the element sulphur, which last must be of importance, since there is in the blood twice as much sulphur as iron. Now, it is precisely these substances that are contained in Uriage water, which, be it also noted, is isotonic with the blood. It is therefore reasonable to suppose that this water is ideally adapted to effect a correct remineralisation. Though it cannot be claimed as a fresh specific, the mercury-sulphur synthesis is, I believe, the most effective method known for the destruction of the syphilitic virus. There is one contra-indication to the combined use of mercury and sulphur—irritability of the bowel. This is probably due to the fact that both these agents are intestinal irritants. It must also be remembered that in nephritis all intensive mercurial treatment is dangerous.

In conclusion, I propose to draw a few comparisons between French and German spas. In France the spatowns seem to have grown up naturally, as do English towns, the comparatively wide village main road developing into the principal street by the erection of the finest buildings, and minor streets shaping themselves as requirements have grown, without any prevision that when the town increased in importance their narrowness would cramp its grandeur. In Germany, whether this foresight has been actually exercised I do not know, but towns when fully developed look as if they had originally been laid out with a view to their ultimate expansion. The result is that German spas have better planned and more spacious public recreation recounds, and that the streets present an air of greater

dignity. In France some of the spas are shamefully kept; the banks of lovely little streams are strewn with ordure, and along the roads there are sights so disgusting that they are best left undescribed. In Germany, on the other hand, we find a cleanliness so scrupulous that it is reminiscent of the deck of a man-of-war.

In France the tendency is for each spa to specialise in the class of cases it seeks to attract. We are given a list of the diseases considered to be amenable to the treatment, and also those which on no account should be sent. Both in selection and rejection, but chiefly in the latter, these lists sometimes seem to be quite arbitrary. As an example, it is stated of one of the springs that the water has no influence above the diaphragm. In Germany, on the other hand, many resorts claim to benefit nearly the whole list of the diseases, and this because, less regard being had to the specific nature of the disease than to underlying constitutional conditions, it is held that these can be beneficially influenced in one way or another by totally dissimilar therapeutic agents. In general balneological equipment the Germans hold a decisive lead. The personnel of the bathhouses is under better discipline, and to secure proper attention incessant tipping is not required, as is so frequently the case in France.

It is frequently said that in France there are more distractions, but I think that if villages and towns of the same size are compared in the two countries there will be found only one difference. In Germany public gambling is forbidden, whereas in France even quite tiny spas provide this form of amusement, if that is the proper name to give to games which steadily transfer bullion from the pockets of the players to those of the managers of the casinos. As M. Blanc of Monte Carlo remarked: "Rouge wins sometimes, Noir sometimes, but Blanc always."

For a short time, during and after the Boer war, Englishmen were liable to insult in either country. That is a thing of the past, but I have not been able to notice that the recent Anglo-French entente or Anglo-German recriminations have made the attitude of the French more friendly or that of the Germans more unfriendly.

My reason for making these remarks and many others scattered through this paper is that the environment and general resources regarded in connexion with the temperament of the patient are often more important than the analysis of the waters with reference to the name of the disease.

Elvaston-place, S.W.

OBSERVATIONS ON ANKYLOSTOMIASIS AND ITS COMPLICATIONS IN EASTERN BENGAL.

BY R. W. BURKITT, F.R.C.S. IREL.

By the evidence of the microscope and the results of treatment one finds that in this part of the country a very large proportion of the illnesses and deaths have as their predisposing factor the ankylostome worm. This climate is hot and very damp, and the country is low lying. There is no proper disposal of fæces: the tanks, rivers, and streams are used in this order—for defæcation, urination, washing of body, washing of clothes, washing of mouth, and then drinking. Pumps are practically unknown; the eating of earth is common; food is only slightly cooked. The habits of the natives are particularly favourable to the spread of this worm. The following observations are very noticeable: that the more low-lying and damp the situation, the more congested with habitations, the more impure the drinkingsupply, the more dirty the habits of the natives, and the closer defecation takes place to the dwellings, the greater will be the number of persons infected by and suffering from ankylostome worms. The reverse of these conditions will show a proportionately smaller number infected. When the soil dries up in the dry season this disease decreases remarkably.

town increased in importance their narrowness would cramp its grandeur. In Germany, whether this foresight has been actually exercised I do not know, but towns when fully developed look as if they had originally been laid out with a view to their ultimate expansion. The result is that German spas have better planned and more spacious public recreation grounds, and that the streets present an air of greater

a day instead of indigestible food twice a day. Rice and pulse as eaten by the native here are of very little value to him. They are boiled for only half an hour and merely the outside surface is digested; hence the residue is large and he therefore eats and defecates largely twice a day (the microscope showing the fæces to be principally made up of undigested rice).

The commonest symptoms here in adults are weakness and irregular diarrhœa; the commonest clinical signs are anæmia (often profound), ascites, and dropsy of the legs and the external genitals (made much worse by their habit of squatting). The most certain position to look for anæmia is the mucous membranes of the mouth, but especially the soft palate; the observer may often be misled by the conjunctiva. There is no condition here which can cause, clinically speaking, such profound anæmia as ankylostomiasis, neither chronic malarial saturation nor chronic dysentery or starvation can do so. In children the signs are often extremely vague and continue to be so until death unless treated; they will always complain of weakness and often of irregular diarrhoea, but they need not show much sign of anæmia. In both adults and children probably the only universal symptom is a feeling of great weakness and the next most common complaint is irregular diarrhea.

In this country it would be quite safe to treat every case of dropsy among natives for ankylostomiasis; in children these cases are often complicated by round worms, but it is more likely that the ankylostome and not the round worm causes the œdema. Unfortunately this disease is particularly common during gestation, probably on account of the incurable native habit of eating clay during that period and on account of the mother staying so much at home in her fæcally infected area. In these cases the prognosis is bad for both mother and child if not treated at once; either miscarriage takes place at a late period of gestation or the child is born dead or dies soon after birth, or the mother dies during labour (generally from hæmorrhage), or after labour

from many complications.

The two most frequent accompaniments of ankylostomiasis in these parts are amobic dysentery and ulcerating mouth. In the dysenteric complication the microscope generally shows besides the ankylostome eggs, entamœbæ coli, entamœbæ hystolyticæ, balantidia coli, and myriads of bacilli. A mixture of ankylostomiasis and tropical dysentery in a previously ill-fed person, as nearly all natives are, is a most serious complication, and one that requires very delicate handling. This condition is just as common in children as in adults, and both invariably die if untreated, some quickly, while others hang on in a chronic state of absolute misery for some time, infecting all about them. There is no more awful picture of utter wretchedness and hopelessness than the native infected with ankylostomes and dysenteric amœbæ, and there is no disease where the prospect is more hopeless than here unless they are removed to an institution with strict supervision. In those cases which die rapidly the stench given off by the gangrenous and ulcerating bowel, mouth, and body of the poor wretch is unbearable.

The majority of natives in this damp, relaxing climate suffer unknowingly from suppurating gums, the Babu class perhaps particularly so. Europeans, unless they use some strong antiseptic tooth powder, nearly always suffer in this way. Unaware of what is wrong they come complaining of any of the following: bleeding from the gums, sore mouth, lips, tongue, and throat; ulcers on the lips, tongue, or throat; foul-smelling breath which someone else has noticed. Owing to the relaxing climate, no matter how well the teeth are brushed, unless an antiseptic is used the gums will eventually suppurate and fall away from the teeth, leaving a deep pocket of pus all round the mouth. The disease progresses until the teeth, which are generally perfectly sound in themselves, get loose and fall out from want of support of both gums and bone at either side. The gums and underlying bone, owing to their chronically in-flamed and suppurative condition, gradually undergo contraction, absorption, and other changes, until the very root of the tooth becomes visible. Glandular abscesses and collections of pus in the planes of the neck are common results of this oral condition, although every tooth in the head may be absolutely sound. When ankylostomiasis supervenes on this state the mouth gets gradually worse and worse, until the patient eventually has ulcers, or partial or wholesale gangrene of the lips, cheek, or tongue, always beginning in

that position which is in continual contact with the worst part of the originally infected gams. It is not uncommon to see nearly the whole tongue slough away or the whole of one cheek or lip.

Again, in dealing with a number of natives with this mouth condition the medical man will often be called to see a case of ankylostomiasis in which there has been steady but slow bleeding from ulcerated gums for several days without intermission. The patient is generally at death's door when he is seen, bled almost to the last drop, and unable to speak. Superficial necrosis of the jaw bone is also common. affections of the mouth are not nearly so frequent in children as in adults. With a native who has no idea of sanitation and is not sufficiently educated to carry out the simplest directions, treatment of these cases outside a strictly

supervised institution is impossible.

As to treatment of ankylostomiasis in this neighbourhood I have nothing new to say. This point only would I emphasise—that, unless the patient is under strict supervision on a purely milk diet, in bed and with the bowels kept gently open by salts for at least two days previous to giving the drug, there will not be thorough eradication, no matter what anthelmintic is used. I use β naphthol in 30-grain doses every two hours for three times on a completely empty stomach and bowels in the morning, and then a big dose of castor-oil two hours after the last administration of the drug. This means nothing in the stomach in the way of nourishment from the evening before till about 3 P.M. next day.
Oil of eucalyptus I find equally efficacious, but the native
dislikes the taste. In the dysenteric complication I first kill the amœbæ with ipecacuanha powder and then undertake the treatment of the ankylostomiasis. For the suppurative, ulcerative, and gangrenous conditions of the mouth no drug is worth mentioning in comparison with peroxide of hydrogen. It cleans everything quickly. I generally order the 10 vol. liquid to be used in the strength of 1 in 3 of water, the solution to be made on the spot as it deteriorates rapidly. For constant and continuous bleeding from the gums there is only one remedy, and it is invariably and quickly successful. It is calcium chloride given in one-drachm doses every two or three hours in plenty of water till the bleeding stops, which always occurs after one or two doses. Probably the reason why this hæmorrhagic condition is so common in this particular neighbourhood is because of the great want of calcium salts in both the water and earth, man and animals suffering greatly from the want of it.

The stamping out of, or the lessening of, this disease means merely the proper disposal of fæces. The adoption of this implies a little primary knowledge about the life-history of the ankylostome worm. Why, when the sick-rate and the death-rate from this disease are so great, cannot all children in infected districts be taught in school the few simple This and a few items about the facts about this worm? spread of water and fly-borne disease, such as cholera and dysentery, would be of much more value than all their other learning put together.

Chandkira, Sylhet District, Eastern Bengal.

A RECENT CASE OF TYPHOID SPINE. BY C. JAMES WILSON, M.B., B.C. CANTAB.

THE following is an account of a recent case of posttyphoid spinal disease, a sequela of typhoid fever described by most writers on the subject as "typhoid spine." I am indebted to Mr. C. W. Mansell Moullin, under whose care the patient was treated at the London Hospital, for permission to publish the case.

The patient, an officer in the Mercantile Marine, aged 28 years, developed typhoid fever on Nov. 20th, 1906, while at sea; he was landed at Bombay, and after five weeks in hospital and ten days convalescence he rejoined his ship on Jan. 24th, 1907, apparently completely recovered. During his convalescence he had suffered from backache, but this entirely disappeared. The first definite sign of the sequela occurred three months later, in April, when after some sudden exertion he was seized with severe pain in the back, lesting about a minute. Three days later the same pain recurred while he was sitting still, and during the subsequent days he suffered from aching in the back on turning out of his bunk

in the morning, the pain wearing off with exercise. He continued duty for a week, but this backache becoming steadily worse he was at length incapacitated, and again entered hospital in Bombay on May 6th. Of his condition and progress while in hospital the only information is as follows. His temperature for the first week was from 100° to 102° F.; his chief symptom was severe pain in the muscles of the small of the back, always worse on the left side, the pain extending round to the abdomen and being accompanied with cramps of the abdominal muscles. There were no "starting pains," but there was always intense pain on waking if the patient had turned on his side during sleep. On May 12th he was operated on for supposed abscess in the region of the left kidney. During June there were two periods of high pyrexia, the temperature rising to 104° for three days on each occasion; the pyrexia was ascribed to malaria, from which the patient had previously suffered, although on these occasions there was no shivering fit, the only associated symptom being headache. Eventually the patient was sent to England, and on July 31st was admitted into the London Hospital. By this time the severity of the pain had subsided, and no further spasms of acute pain occurred. At this time the local condition was as follows: there were marked rigidity of the dorsi-lumbar spine, pain on jarring the spine, and deep tenderness over the first A radiograph and second lumbar transverse processes. showed much thinning of the intervertebral discs, with signs of necrosis in the vertebræ, and many osteophytes around them. An examination made to determine the patient's opsonic index with regard to the tubercle bacillus showed a high index and no evidence of auto-inoculation with tubercle toxins. On the other hand, an examination of the blood with reference to the typhoid bacillus showed a marked reaction to Widal's test, instant agglutination occurring with a dilution of 1 in 100, agglutination also occurring with a dilution of 1 in 1000. While in the London Hospital the symptoms completely disappeared, the latest persisting being rigidity. His recovery was uninterrupted, and he returned to sea at the beginning of 1908, since when he has enjoyed normal

This case presents the chief features common to the cases of "typhoid spine" described by American and German writers. Of these cases there are now so many recorded as to make it clear that the dorsi-lumbar spine is a not very uncommon site for the late activity of the typhoid bacillus. From a study of these cases the course of such an infection may be summarised as follows. During convalescence from typhoid fever, at a varying interval after the fall of temperature, which interval may be as much as three months, as in the above case, the patient complains of pain in the back. This pain may have developed gradually from a slight aching noticed when the patient first began to walk, or it may have set in later, perhaps as the result of some strain. The patient is quite incapacitated and confined to bed. There is intense pain on any movement of the lumbar spine; consequently there is rigidity of this part, and during any movement liable to involve flexion or rotation of the spine, such as the act of turning over in bed, he fixes himself by pressing his hands on his hips. ing pains" occur during sleep. There may be tenderness over one or two vertebræ, but often this sign is absent. There may be cramps of the abdominal muscles, or girdlepain, or perhaps nervous derangements in the legs, such as alteration of the knee-jerks. A fulness of one or other flank may be perceptible; presumably this sign was present in the above case when the diagnosis of perinephritic abscess was made. In time there may appear a prominence of one or more lumbar vertebral spines, resulting in a permanent kyphosis. As regards constitutional symptoms, the temperature is generally raised, and the patient's condition suffers severely from pain and sleeplessness. After weeks or months of acute suffering, with remarkable intermissions and exacerbations of the intensity of the pain, the symptoms eventually subside, and complete recovery, with possibly some persistent kyphosis, results.

The condition can only be explained by assuming an invasion of the spinal tissues by the typhoid bacillus. The chief symptoms—namely, the excessive pain and consequent rigidity, must be due to acute inflammation of the periosteum and spinal ligaments. In some cases there is no evidence of any further lesion, and hence the

term "perispondylitis," which has been applied to the condition by American writers. But in other cases there must also be an osteo-myelitis of the vertebral bodies; for instance, in this case now reported the radiograph showed plainly rarefaction of the bone, and in the case which I reported three years ago 1 there resulted permanent kyphosis with prominence of the second and third lumbar vertebræ; such signs indicate destruction of bone. Again, those cases which exhibit nervous symptoms indicate extension of the inflammation to the membranes of the spinal cord. Why should the lumbar spine be a favourite site for this specific periositiis or ostellis? The typhoid bacillus has been demonstrated in great numbers in the medulla of the vertebræ after death from typhoid fever; perhaps the muscular weakness which follows a severe attack renders the ligaments of the lumbar spine particularly susceptible to injury from even a slight over-exertion, such injury affording opportunity for the activity of bacilli already present just beneath the periosteum. On this hypothesis the condition originates in a manner similar to the common post-typhoid periostitis of the tibia or other bone. On the other hand, it is conceivable that the proximity of infected lumbar lymphatic glands may have a bearing on the question.

Cobham.

A CASE OF ENDEMIC CEREBRO-SPINAL MENINGITIS TREATED BY INTRA-SPINAL INJECTIONS OF FLEXNER'S SERUM; RECOVERY.

By D. D. ROSEWARNE, M.R.C.S. Eng., L.R.C.P. LOND., LATE HOUSE PHYSICIAN, ST. MARY'S HOSPITAL, W.

A MALE child, aged 5 months, was admitted into St. Mary's Hospital, under the care of Dr. A. P. Luff, on April 27th, 1909, with well-marked signs of cerebrospinal meningitis. The mother stated that seven days before admission the child had had a "fit," and three days later she noticed that the head was "drawn backwards." There had also been several bouts of vomiting and "screaming fits." The bowels had been regular. The child was breast-fed from birth and there was no history of previous illness. Two children of the family, aged 5 years and 5 months respectively, were said to have died from meningitis in 1907.

On admission the temperature was 101.20 F., the pulse 144, and the respirations were 44. The child was wellnourished and weighed 16 pounds 8 ounces. There were marked irritability and restlessness, and extreme retraction of the head was present. The pupils were moderately dilated, equal, and the reaction was brisk; there was no optic neuritis or squint, but vertical nystagmus was noted. The abdomen was slightly distended and the superficial abdominal reflexes were well marked. Kernig's sign was clicited and the legs were drawn up. The knee-jerks were brisk and ankle clonus was absent. Tache cérébrale was present. There was marked bulging of the anterior fontanelle. respiratory and cardio-vascular systems were normal. lumbar puncture was performed on the day of admission and 3 drachms of slightly turbid fluid were withdrawn for bacteriological examination. The report of Dr. B. H. Spilsbury showed that the diplococcus meningitidis was present in considerable numbers and that the polymorphonuclear cells were largely in excess. Agglutination tests demonstrated the fact that the case was one of endemic One week after admission lumbar puncture was again performed, 8 drachms of turbid fluid being withdrawn, and 10 cubic centimetres of Flexner's serum were injected into the spinal canal. Two days later the child vomited for the first time since admission. The temperature showed a little less variation than it did before injection and the infant seemed a little brighter and less irritable. After another week further lumbar puncture was performed, 6 drachms of fluid being withdrawn and 15 cubic centimetres of Flexner's serum being injected. Vomiting still continued, but

the periosteum and spinal ligaments. In some cases there is no evidence of any further lesion, and hence the August, 1906.

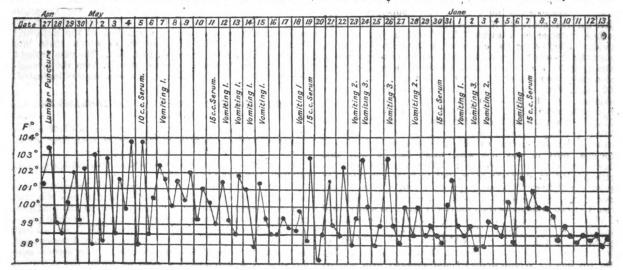

the child began to take more notice of his surroundings. On the fifth day after this injection an urticarial rash developed, which disappeared in a few hours. Eight days later a third injection was given; 15 cubic centimetres of serum were again introduced into the spinal canal after withdrawing 6 drachms of fluid. The latter was less turbid than hitherto, while the bacteriological report showed that relatively fewer diplococci were present. Vomiting still continued, and during the next week the temperature varied a good deal, as shown in the accompanying chart, which records the temperature throughout, and also shows the effect of the injections. Head retraction at this date was less noticeable.

1

P.

retraction practically disappeared, the infant's condition improved daily, and he appeared to be quite normal. All the signs of meningitis ceased, and there was no appearance of imbecility. The child, who is still under observation, was quite normal when last seen—viz., two months after discharge from the hospital.

It may be worthy of note that no drugs were given except the pulvis ipecacuanhæ alluded to and an occasional purge. Undiluted citrated milk was given in appropriate amount throughout. The child lost $2\frac{1}{2}$ pounds in weight during his illness, but on discharge he weighed the same as on admission—viz., 16 pounds 8 ounces. Whether recovery was due

Ten days after the last injection a fourth was given, 15 cubic centimetres of serum again being introduced. Vomiting continued to be troublesome, and for three or four days the child had severe diarrhoea, but this was controlled by the administration of small doses of pulvis ipecacuanhæ compositus. As will be seen by the chart, the temperature rose to 101·8°, but on the following day became normal, and after rising to 103° six days after the injection again reached normal. The fifth and last injection was given six days after the fourth, upon which the temperature fell to normal and remained thereabouts for about seven weeks, when the child was discharged as cured. During this period the head

to nature, to repeated lumbar punctures, or to the use of Flexner's serum cannot be definitely stated until statistics are available. From observations it appears that the serum will be more extensively used, and many cases seem to have benefited from its use in New York and elsewhere. Whether the child will be normal in intellect in the future cannot be decided except by means of observation for many years, and it is hoped that this will be carried out as it seems probable that in this case it will be practicable. In conclusion, I must thank Dr. A. P. Luff, through whose courtesy and kindness I am enabled to publish this case.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

Presidential Address.—Electro-therapy in Gynæcology.—
Placenta Prævia.

A MEETING of this section was held on Oct. 14th. The Presidential Address having been delivered by Dr. H. MACNAUGHTON-JONES on Pain Associated with Disorders of the Female Generative Organs,

Dr. J. Curtis Webb read a paper on the Use of and Indications for Electro-Therapy in some Gynæcological Affections. He remarked that in the treatment of gynæcological affections by electro-therapy different types of currents must be employed to produce different therapeutic effects. A rapidly interrupted induced current produced a sedative effect, and was useful in neuralgic conditions. A current with slow interruptions should be used to tone up relaxed muscle. When bare metallic electrodes were used they produced their action by ionisation of the metals; local effects were produced, and the result would vary with the valency and composition of the electrodes. Thus a positive zinc electrode amalgamated with mercury had a strong antiseptic action. Metallic ions were driven in, and the acid radicles of the fluids of the body being attracted, they exercised a cauterising and hæmostatic effect. If the electrode were negative the basic components

of the body fluid were drawn out, producing a solvent or congestive effect. When the electrodes were covered by nonmetallic substances, such as wool, there was no ionisation of metallic particles, and so no local effect was produced. Dr. Webb said that treatment by static electricity was of great value in certain cases, more especially when a general rather than a local effect was desired. In inflammatory diseases of the vagina or vulva, copper or zinc ionisation, used in addition to ordinary methods of treatment, was of great value, and he described a special electrode suitable for these cases. The methods of obtaining and controlling currents and the various types of electrodes to be used were also described. Methods of treating amenorrhoea, scanty menstruation, and dysmenorrhoea were also mentioned. In inflammatory affections of the uterus brilliant results might be obtained by zinc-mercury ionisation, which would probably largely take the place of curettage Much might be done for simple inflammatory diseases of the tubes and ovaries. As a rule, in these cases a course of abdomino-vaginal applications should precede intra-uterine treatment. Brief notes were given of a series of cases exemplifying these methods of treatment.—In a discussion which followed Mr. SPANTON expressed his surprise that in a discourse on electric treatment in gynæcology no mention had been made of Apostoli who was one of its chief pioneers. adopted Apostoli's treatment in cases of uterine myoma with hæmorrhage with most excellent results 20 years ago, but found the method somewhat cumbersome and difficult to carry out in hospital practice, and expensive and tedious in private patients, and these were probably the chief reasons why it had somewhat fallen into disuse. - Dr. AMAND ROUTH said that some years ago, when he had more time, he adopted

the methods advocated by Apostoli, and he had found real benefit from the use of the positive intra-uterine pole with a current of 60 to 120 milliampères in cases of uterine hæmorrhage due to "endometritis" or fibroids or subinvolution. He felt, however, that the time, trouble, and expense of the treatment were not justified by the results obtained as compared with those following ordinary methods of treatment. In severe cases of chronic subinvolution and endometritis curettement was preferable, and accomplished much more than mere removal of hypertrophic mucosa as suggested by Dr. Webb.-Dr. HERMAN STEDMAN said that he had selected some half-dozen cases of chronic endometritis and cervical catarrh, and had endeavoured to stop the discharge by means of ionisation with zinc and copper, but that after six treatments of 600 milliampère-minutes he had only in one instance been successful. The dose used was the standard adopted on the continent, and was arrived at by using the strongest current the patient could bear and maintaining it for a sufficient time, which when multiplied in minutes by the number of milliampères resulted in a total of 600—e.g., 30 milliampères for 20 minutes = 600 milliampère minutes.—Dr. F. Howard Humphris said that as an adjunct to gynæcological treatment electro-therapy was invaluable. He had used it himself for several years. Various illdefined pelvic pains and backache could be relieved as surely with the faradic current as with a hypodermic injection of morphia, only it was not with every faradic coil that these results could be obtained; different lengths of wire were needed in different cases, but in most conditions in which a sedative effect was required a long fine wire coil, used with a bi-polar vaginal electrode, would give relief in from 15 to 20 minutes.—The PRESIDENT said that a good deal of bias and prejudice had existed with regard to electrical treatment in gynæcology. This might be explained by our ignorance of the manner in which the various kinds of electricity operated in their therapeutical applications. late Dr. Charles Routh, almost simultaneously with Cutter, in the "sixties" advocated electrical treatment; then came Tripier, and, following him, Apostoli. When the latter's methods and results were published he (the President) had procured all his appliances and had tried both electro-causis and the faradic treatment. For the latter he used different coils and the high-tension battery, with the various sized coils recommended by Apostoli, which had just been referred to, and with the vaginal and intra-uterine bi-polar electrodes. With regard to electro-causis, he had so serious a result in one case that he abandoned it altogether. The patient suffered from cataleptic and hystero-epileptic attacks, associated with profuse hæmorrhages from a fibromatous uterus. Every practical precaution was taken in the application of the current both as to strength and antisepsis. At first she apparently did not suffer from the treatment. A skilled electrician was present at each sitting, which was given in bed; suddenly she developed symptoms of peritonitis, which proved fatal. Apostoli pointed out that this class of patient was particularly susceptible and that the treatment was attended with risk. With regard to faradisative the statement was attended with risk. tion in amenorrhœa and dysmenorrhœa, he had varying results both with the constant and faradic currents. many cases, as might be expected, there was no influence on either the flow or the pain.

Dr. J. M. MUNRO KERR (Glasgow) reported a case of Cæsarean Section for Placenta Prævia, The patient, who was 28 years of age, was seen with Dr. J. McEwan, of Helensburgh; she was one week from full term, and had been curetted by Dr. Archibald Donald of Manchester for fibroid tumours of the uterus. She was considerably better for this operation, and soon after became pregnant. For a few weeks before full term hæmorrhage occurred from the uterus on several occasions, and an examination under an anæsthetic revealed the presence of a centrally situated placenta prævia. Removal of the uterus was likely to be soon required, and the chance of any further pregnancy was small. The friends having given their consent, he therefore performed Cæsarean section, delivering a living child. The uterus was then removed by supra-vaginal amputation. It contained a number of fibroids, the largest one on the anterior wall being about the size of the closed fist. The patient made a good recovery except for a slight attack of pleurisy on first getting up.-Sir WILLIAM SMYLY said that where placenta prævia was complicated by uterine myomata Cæsarean section followed by hysterectomy was undoubtedly the correct line of treatment, and he congratulated Dr. Munro Kerr upon its success.

-Dr. W. S. A. GRIFFITH said that he had been convinced for some years that certain special cases of placenta przevia would be best treated, both in the interests of the mother and child, by Cæsarean section. In January, 1905, he was called by Mr. A. M. Crabtree of Weybridge to a woman, 38 years of age, who had had two severe hæmorrhages. The child was lying in the first position above the brim, the cervix closed and tough, the pelvis of normal size, and the vagina narrow. Both husband and wife expressed the wish that the life of the child should be saved, and readily agreed to Cæsarean section, which was at once performed. Both mother and child did well.—The PRESIDENT said that the case brought before them raised the all-important question of the justification for Casarean section in placenta pravia. It had quite recently given rise to one of the most important discussions at the McDowell Centennial Anniversary in America, in which their late president, Dr. Herbert Spencer, took part. The case brought forward by Dr. Munro Kerr was obviously, from the myomatous complication, one in which the operation was indicated.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Exhibition of Cases.—Some Liver Conditions in Childhood.— Procumococcal Infection in an Infant simulating Generalised Tuberculosis.—Exhibition of Specimens.

A MEETING of this section was held on Oct. 22nd, Dr. G. A. SUTHERLAND being in the chair.

Mr. A. Manuel showed two cases of Anterior Poliomyelitis involving the Four Limbs. The first case was that of a child, aged 1 year and 8 months, in whom the condition developed suddenly after a slight injury. The child's temperature when taken to the hospital was 100° F. and all four limbs were paralysed. Some improvement had occurred in the arms since the child was admitted. The second case was that of a child, aged 1 year, in whom the condition resulted from a sudden illness on August 15th; considerable recovery in the arms had already occurred, but there was still complete paralysis of all the extensors of the foot and leg.

Mr. A. RALPH THOMPSON showed a case of Extracapsular Fracture of the Neck of the Femur in a boy aged 6 years. The injury had resulted from a fall. The diagnosis was at first very obscure, but a skiagram revealed the true nature of the injury. The case had been treated by extension and Thomas's hip splint.

Dr. F. W. HIGGS showed for Mr. J. HOWELL EVANS a case of Congenital Hemidystrophy. The patient was a child aged 1 year and 10 months. When only a month old it was noticed that the left side of the tongue was larger than the right, and later that there was asymmetery of the abdomen. At the present time a marked difference could be observed between the sizes of the two sides of the body. It was pointed out that the condition in this case was progressive.—Dr. F. PARKES WEBER and Mr. J. P. LOCKHART MUMMERY discussed the case.

Dr. W. ESSEX WYNTER showed a case of Chloroma. The patient was a female, aged 3‡ years, showing very marked facial deformity which had been noticed since the middle of May. The face was unusually large and bony, with shiny, tense skin over the malar bones, and marked exophthalmia, especially on the right side. The glands about the neck were enlarged. The blood count showed red corpuscles, 3,630,000; white, 30,000; hæmoglobin, 56 per cent.; and lymphocytes, 66.2 per cent.—Dr. Sutherland, Dr. T. R. C. Whipham, Dr. F. Langmead, Dr. E. I. Spriggs, and Mr. Sydney Stephenson discussed the case.

Mr. Mummery showed a case for diagnosis. The patient was a boy, aged 6½ years, with a spastic gait and very marked contraction of each tendo Achillis. He was only able to walk on the tips of his toes.—Dr. Spriggs referred to a similar case which had been regarded as one of hypertonia.—Dr. R. C. Jewesbury pointed out that the case might be one of diplegia, as there were well-marked kneejerks and Babinski's sign was obtainable.—Dr. Higgs regarded the case as one of spastic paraplegia.—Dr. Sutherland pointed out that there should be in that case some mental defect.—Mr. Mummery, in reply, said that there was no evidence of any mental defect.

Dr. A. DINGWALL FORDYCE communicated some notes on the Pathology of some Liver Conditions in Childhood,

with a report of three cases. Case 1 was that of a child, aged 7 years, with sub-acute yellow atrophy of the liver. year ago the child had an attack of jaundice and since then had complained of pain in the left side of the abdomen. Seven weeks before death the child began to look ill and the abdomen was noticed to be swelling. There were diarrhosa and vomiting, cedema of the back, paresis of the left leg and left side of the face, and a squint. The temperature was 99° F., and the pulse was 144. Post mortem slight pleurisy and pericarditis were found. There was some bile-stained fluid in the peritoneal cavity. The stomach was dilated, and in the ascending colon there was an acute tuberculous ulcer. The liver was greatly reduced in size and almost flat, and its surface was irregular with well-marked yellow nodules. Microscopic examination showed yellow areas of hyperplasia and much fibrous tissue. Case 2 was that of a girl, aged 8 years, who was admitted to the hospital with caries of the dorsal spine. She died from persistent vomiting a few days after admission. The post-mortem examination revealed a fatty condition of the liver, which weighed 460 grammes. Case 3 was that of a boy aged 4 years and 8 months. The child was first seen on account of digestive troubles and on examination it was noticed that the liver was much enlarged. The child died after an operation which revealed malignant disease of the liver. At the postmortem examination the liver was found to weigh 4½ pounds and to be studded throughout with new growth. A tumour was discovered in the ileum about 1 foot from its lower end. The kidneys were enlarged.

Dr. J. WALTER CARR read a paper entitled "A Case of Pneumococcal Infection in an Infant simulating Generalised Tuberculosis." The patient was a child aged 15 months. The case was at first thought to be one of acute pneumonia, but when after several weeks the condition remained unaltered with an irregular temperature it was thought to be one of general tuberculosis. Calmette's test gave a negative result. The child died and the necropsy revealed no trace of tubercle but a general pneumococcal infection. There was well-marked pericarditis. The right lung was universally adherent and the upper lobe showed old unresolved pneumonia; the left lung was also adherent. The peritoneal cavity contained about a pint of semi-purulent fluid.

Dr. Higgs showed a specimen from a case of Lymphosarcomatosis. The specimen showed an appendix infiltrated with lympho-sarcoma. The kidneys also showed diffuse infiltration with lympho-sarcoma cells.

Mr. Ivon Back exhibited a specimen from a case of Acute Inflammation in an Appendix, involuted into the lumen of the cæcum, which then formed the apex of an intussusception. The specimen was removed from a girl, aged 8 years, by operation, the patient recovering.

MEDICAL SOCIETY OF LONDON.

Legislation in Regard to Anasthetics.

A MEETING of this society was held on Oct. 25th. Dr. SAMUEL WEST, the President, being in the chair.

Dr. FREDERIC HEWITT read a paper, which is printed in full in this issue of The Lancer, p. 1266, on the Need for Legislation in Regard to Anæsthetics and the lines upon

which it should take place.

The PRESIDENT said that, considering the risks involved in the administration of anæsthetics, it was necessary to consider the present want of regulation in the matter.

Mr. L. MATHESON contended that to restrict qualified dentists from the administration of anæsthetics for dental operations was inconsistent, unnecessary, and prejudicial to the best interests of the public. The diploma granted to qualified dentists was a guarantee to the public that they were fit to practise dental surgery and to administer anæsthetics for dental work because it was an integral part of dental surgery. For dental purposes nitrous oxide was generally given, and he asked what evidence was there of danger to the public in qualified dentists giving gas. He had not yet heard of any fatality that had occurred in the hands of a qualified dentist. He did not admit that the general practitioner was a better anæsthetist than a dentist, and he thought that in a large proportion of cases the practitioner was not better than the dentist. The dentist as a rule was all the examining bodies have come into line in the United better trained in giving anæsthetics than the medical man. Kingdom and have made instruction in anæsthetics a

Referring to giving an ansesthetic and operating at the same time, he said that that procedure would gradually disappear.

Mr. A. L. FLEMMING said that supposing an emergency happened at a dental operation, such as choking from a foreign body in the larynx, would a dentist be qualified to deal with the case? There was nothing in his training which would ensure his being qualified to deal with such an emergency. If the Bill were passed as suggested by Dr. Hewitt that difficulty would be met. He gave details of how two Bristol dentists considered that the Bill from the point of view of the nation was satisfactory, and it was not thought that the dentists had anything to complain of if they were restricted from giving gas.

Dr. DUDLEY W. BUXTON said that Dr. Hewitt was endeavouring to secure that any man who gave an ansesthetic should be capable of doing so in a satisfactory manner. A Licentiate in Dental Surgery was fully qualified to carry out this work in dental operations, for he was competent to give such an anæsthetic and to act with rapidity and decision in case of accident. He did not consider that any medical man was necessarily qualified to give an anæsthetic in the same manner as a skilled anæsthetist, but he did think that the ordinary qualified dentist was in his own particular walk of life a skilled giver of anæsthetics in his own particular line. In the case of emergencies any man might make a mistake, and the highly qualified medical man was open to the charge of not always doing the right thing as well as the dentist. In regard to a dentist operating and giving gas at the same time, that dual procedure was constantly occurring, not only in country places, but also in towns, and medical men must be prevented from doing the same thing. It was drawing a red herring across the scent to say that that was an argument against dentists giving nitrous oxide gas.

Mr. J. G. TURNER said that the dangers incidental to the giving of anæsthetics were such that they could not expect the Licentiate in Dental Surgery to cope with them. In two years' hospital work it was impossible to imagine a dentist learning enough clinical and surgical knowledge to deal with emergencies. He was certain that the danger was just too great to allow the unrestricted administration of nitrous oxide gas by a Licentiate in Dental Surgery.

Mr. A. W. MAYO ROBSON pointed out that when operating in the country he had experienced considerable difficulty in consequence of general practitioners being unskilled in giving anæsthetics. In regard to dentists giving anæsthetics great difficulties must arise if that were prohibited, for dentists have for many years given gas and had given it extremely well. He thought it would be very difficult to districts. He considered that a Licentiate in Dental Surgery was sufficiently qualified to give an ansethetic in dental work.

Dr. J. VINCENT BELL said that in regard to country districts the dentist was often found to be more expert in giving an anæsthetic for a dental operation than the raw country doctor.

Mr. H. BELLAMY GARDNER declared that it must not be forgotten that public confidence in this matter should be maintained not only by individual but also by collective effort.

Dr. J. F. W. SILK asked for trustworthy figures to show that there were an enormous number of deaths from the administration of a general anæsthetic by unqualified persons. He wanted some reliable facts to show that legislation was necessary. One difficulty in regard to the Bill was in reference to its being put into force. If such action rested on the man in the street then legislation was of no value whatsoever. To take out of the hands of dentists the power of being able to administer nitrous oxide gas would be lamentable, and to place the administration of gas in the hands of a qualified medical man who possibly had never seen gas given would be a great misfortune.

Dr. HEWITT, in his reply, pointed out that it was impossible to supply reliable statistics concerning deaths under anæsthetics. In answer to Mr. Matheson, he gave details of a certain dental hospital where gas was given by qualified medical men in over half a million cases. On one occasion, through the absence of the medical man, the gas was administered by a qualified dentist, and on that occasion a fatal accident resulted. Within the last two years practically

necessary part of the medical curriculum, so that in future medical men will be fully instructed in the giving of ansathetics.

OPHTHALMOLOGICAL SOCIETY.

Presidential Address.—Pathological Pedigrees.—Exhibition of Cases.

A MEETING of this society was held on Oct. 21st, when Dr. G. A. BERRY, the new President, who occupied the chair, delivered his Presidential Address. He first expressed his keen appreciation of the honour the society had done him in electing him to the presidential chair. As one progressed the truth of the maxim quot homines tot sententia became more and more evident, and it was not only educating but inspiring to realise the steps which had led to the great advances and to get some idea of the manner of thinking and the intellectual environment of the author. was scarcely anything so fascinating as the history of medicine. For many advances they could claim something more than rediscoveries; they were new discoveries, logical deductions from carefully collected observations and experiments, not merely irresponsible speculations. The practical man was an empiric, but now the science of medicine had not only overtaken but greatly outstripped the art; and, indeed, there were many reasons for treatment lagging behind. Practical therapeutics was one of the most imperfect of the arts. Surgery was perhaps the least subject to individuality, and it was in surgery that the greatest advances in treatment had been made of recent years. But the advances resulting from antiseptic surgery had led to over-confidence in, and too frequent resort to, operative interference, and that was no doubt favoured by the public. That, however, was merely a swing of the pendulum too far, and would right itself in time. The art of surgery had advanced, and was still advancing, in a way and to an extent it had never done before. The functional activity of the eye could now be estimated with every refinement. But beyond increased safety in operations, the advances in ophthalmic surgery had never been commensurate with those in general surgery. He then went on to deal in detail with the aims and results of some of the operations for cataract. In the Middle Ages the monks paid scrupulous attention to cleanliness of instruments, and they had an anæsthetic with which patients were treated, sometimes to the extent of losing consciousness, when painful operations were performed. Since 1866 no radical change had been made in the methods of cataract extraction which found general acceptance. Something better in the treatment of cataract was at least conceivable; there might be cure without operation, or prevention altogether might be possible. Useful as was iridectomy in the treatment of glaucoma, further advances in that direction might be made in the future. He did not think irido-dialysis would ever be revived. Nearly all the surgical interferences now in use for trachoma had their prototypes in ancient times. The treatment which gave the best results in the more severe chronic cases was now often employed in cases where it came to be an unnecessary mutilation. He regretted the tendency of the public to go to the optician for defects of vision, because the optician could not detect and treat the pathological condition which often underlay them. The President then entered into a historical survey of treatment of eye conditions, paying special attention to the Hippocratic school. Polypharmacy was largely practised by the ancients because they did not know the values or chemical reactions of drugs. He believed the use of mydriatics had been overdone. The advantages of inducing hyperæmia had long been known empirically, but Bier had now put the matter on a scientific basis. The efficacy of ionisation was very real, and though the practice was yet in its infancy there were many possible developments in the future, and the same was true of X rays and radium. In trachoma it was doubtful how far those remedies would take the place of surgery. In conclusion, the President declared himself a believer in the great future of medicine, both preventive and remedial, in which treatment by sera and antibodies which counteracted and stimulated the activities of the organism would play a great part.

Mr. PRIESTLEY SMITH made two communications, one a

Pedigree of Congenital Discoid Cataract. In connexion with the last named Mr. Smith said that it almost exactly conformed to Mendel's law.—The paper was discussed by Mr. E. NETTLESHIP, Mr. R. W. DOYNE, Mr. J. HERBERT FISHER, and Mr. E. TREACHER COLLINS, and Mr. PRIESTLEY SMITH

replied.

Mr. N. BISHOP HARMAN showed a new Retractor for use in Excision of the Lacrymal Sac; also Symmetrical Discoid

Cataract in two sisters.

Mr. G. T. BROOKSBANK JAMES showed a case with very Unusual Fundus Appearances, and two cases illustrating Irido-sclerectomies by the Open Method in Glaucoma. He said that he was somewhat pleased with the latter operation, so far as he had gone, though some difficulty was caused by a certain amount of oozing from the vessels, which had to be stopped before the incision was made.

Mr. H. B. GRIMSDALE showed a case of Retraction of the

Eyes associated with the act of Winking.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

Exhibition of Clinical Cases.

THE annual general meeting of this society was held in the library of the Royal Victoria Infirmary, Newcastle-on-Tyne, on Oct. 14th, the retiring President, Dr. R. S. PBART, being in the chair.

Mr. E. H. DAVIS of West Hartlepool was elected President of the society for the forthcoming session, and was invested

with the badge of office.

Dr. THOMAS BEATTIE showed: 1. A man, aged 54 years, with Paralysis Agitans, whose case had been under observation for five years and in whom there was the typical general posture with retropulsion, exalted knee-jerks, tremors of the neck and facial muscles and of the legs, but none of the usual rotatory movements of the forearms and 2. A coloured sailor from a Brazilian warfingers. ship suffering from Diffuse Peripheral Neuritis, affecting especially the posterior interosseous nerves of the forearms and the anterior and posterior tibial nerves in the legs. Care had been taken to exclude lead and the other usual toxic causal agents, and the man had come from a ship where there had been several cases of beri-beri. 3. Two cases of Specific Aortitis, with fusiform dilatation of the aorta, aortic regurgitation, and anginal attacks. Dr. Beattie brought forward these two cases in order to discuss the cause of these anginal attacks. He raised the following questions: (a) Were the anginal attacks due to the dilatation of the aorta similar to the pain of aneurysm and reflex through the sympathetic? (b) Were they due to the lack of proper distension of the coronary arteries, and consequent ischæmia of the heart muscle resulting from the aortic regurgitation and imperfect filling of the sinuses of Valsalva? (c) Were they due to actual narrowing of the coronary arteries from specific endocarditis similar to the specific condition of the aorta?

Dr. A. M. MARTIN exhibited: 1. A case of Femoral Aneurysm in a male, aged about 40 years, cured by extraperitoneal ligature of the external iliac artery with chromicised catgut. The cause was unknown and it produced typical symptoms and signs, also pain radiating from the hip to the knee-joint. The sac was still present but pulsation was absent. 2. An interesting case of "Joint Mouse," the foreign body being a detached piece from the internal femoral condyle. The patient, a male, aged 25 years, when seen complained of symptoms typical of a loose semilunar cartilage. Five months before the operation the toe of his right foot caught against a steel plate in a shipyard. He fell down with his leg doubled up under him; the knee was locked for some time, and complete extension was never afterwards possible. At the operation a large piece of bone measuring $11 \times 1 \times \frac{1}{8}$ inch was found; it was coated with cartilage on its convex aspect, and this exfoliated shell comprised the greater part of the lower aspect of the internal condyle of the femur. Mr. Martin mentioned that he had once before seen a similar case.

Mr. H. BRUNTON ANGUS showed two interesting cases which he had previously treated for Joint Dislocation, and Note on the Making of Pedigree Charts, and the other a both of which had organic nerve lesions: 1. A male, aged about 45 years, came with a sciatic dislocation of the hipjoint. About three months afterwards he returned with a huge mass of new bone growing from the antero-lateral aspect of the upper end of the right femur. This pair less tumour extended upwards into the right iliac fossa and did not implicate the hip-joint. The overlying tissues were very cedematous and the superficial veins were dilated, so that the condition simulated a bone sarcoma. The man presented unmistakeable signs of tabes dorsalis, and the view was therefore taken that the new formation of bone was a parasyphilitic manifestation. 2. The second case was a male, aged 35 years, who 15 months previously came with a dislocation of the shoulder, which was reduced. Recently he was sent to Mr. Angus a second time with a diagnosis of sarcoma of the upper end of the humerus. This diagnosis was based on great swelling and cedema in the region of the right shoulder-joint, together with dilatation of the superficial veins and a marked degree of thickening of the upper end of the humerus. No other joints were implicated, but there was no doubt that it was a monarticular osteoarthritis, and time had confirmed this view. This patient was developing symptoms and signs of general paralysis of the insane.

Dr. Horsley Drummond showed: 1. A middle-aged man with two separate Saccular Anenrysms of the Thoracic Aorta, whose only symptom was pain referred along the left eleventh dorsal segment. There were no physical signs. The diagnosis entirely depended upon the X-ray evidence, and the skiagrams showing the condition were also demonstrated. 2. An elderly male with typical symptoms and signs of Thoracic Aneurysm.

Dr. S. S. WHILLIS showed: 1. A child upon whom he operated three weeks previously for a Chronic Otorrhea of three years' duration and which had produced a Mastoid Abscess with Lateral Sinus Thrombosis. The operation was a modification of Ballance's method, a rectangular flap of the whole posterior wall of the cartilaginous meatus being detached and turned inwards. 2. A case after Removal of a Laryngeal Growth through a Killian's Tube.

Dr. A. PARKIN exhibited: 1. A case of Raynaud's Disease in a young adult female. There was a patch of gangrene on the heel, and both feet and legs were cyanosed. The radial pulse had a very small volume, and Dr. Parkin remarked that he considered this feature more than accidental. 2. An adult male who had Lymphadenoma with Paraplegia. There was a nodular mass in his liver and his legs were paralysed. When the patient first came under notice it was a question whether the paralysis was the result of a spinal lesion or due to the lymphadenoma. Retention of urine supervened, which Dr. Parkin said was a proof of spinal disease.

Dr. R. A. BOLAM showed: 1. A case of Lichen Ruber Moniliformis. The patient was a man who for four and a half years had had an eruption in the groin, in the ham, and in the region of the ankle. eruption underwent little change and was painful at times, especially during weather changes. Itching was not now a marked feature, although present at first. The linear arrangement of the papules comprising the eruption was very striking and strongly suggestive of connexion with nerve areas. The patches appeared to occur in the first to the fifth lumbar areas. 2. A case of Nævus Unius Lateris in a -boy who soon after birth was noticed to have roughened areas of skin on one half of the body. There was now a definite verrucose condition of skin in patches and lines, the arrangement of lesions suggesting a family resemblance to Case 1. The distribution was definitely unilateral, half of the scrotum and half of the penis, for example, being involved. Other areas extensively affected were the posterior scapula and the elbow. 8. Cases of Tinea Barbee and Favus were also exhibited.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—
At the opening meeting of this society on Oct. 20th Dr.
John Campbell (Belfast) gave the inangural address on Sepsis
in Midwifery Practice, Dr. Adam Fulton, the President,
being in the chair. Dr. Campbell said that since more than
2000 women die annually in England and Wales from
puerperal sepsis, accounting for three-fourths of the total
mortality of puerperal conditions, the subject was incontestably an important one and one that appealed to every
general practitioner. The mortality from sepsis in lying-in
taospitals was now as low as 0.1 per cent. or even 0.048 per

cent. (Rotunda Hospital, 1908), which contrasted with a general mortality over the whole country of 0.22 per cent. to 0.23 per cent., although this was understating the case. Probably the true mortality was more nearly that of Manchester, which worked out at 0.56 per cent., or in its worst district as high as 1.4 per cent. The more stringent test of morbidity rather than mortality was now applied to lying-in hospitals, and the same thing had been worked out successfully in private practice. Of a series of 465 cases recently reported in 77 per cent. the temperature never exceeded 99° F. Bacteriological investigations had shown that in a normal puerperal woman before labour the genital tract might be divided into a septic zone below and external to the position of the hymen, an antiseptic but not sterile zone corresponding to the vagina, and a sterile region within the uterus itself. Digital examination and the changes of labour itself might, and frequently did, completely alter these distinctions. Dr. Campbell also dealt with unsuspected sources of infection about nurses, such as gumboil or varicose ulcers, and explained the position he took up with regard to douching. He laid much stress on the value of a sharp, large-looped flushing curette with long handle, to be used in every case where the hand had been introduced within the uterine cavity or where there was any possibility of placental débris remaining behind. He also devoted some time to the prevention of sepsis, where this was favoured by preceding septic conditions about the male or female genital tract.—A hearty vote of thanks was proposed by Dr. H. Michie and supported by Dr. W. R. Smith (Beeston).

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this society was held on Oct. 21st, Mr. C. T. Holland being in the chair.—Dr. J. Hill Abram read a note on a case of Polycythæmia Megalosplenica in a male.—Dr. A. Stookes and Dr. E. E. Glynn related a case of Accidental Hæmorrhage and Chronic Uræmia in which bacillus proteus was found.-Mr. F. A. G. Jeans read a paper based on 10 consecutive cases on which he had operated for Perforative General Peritonitis. There were two cases of perforated duodenal ulcer and eight cases of general peritonitis due to perforative or gangrenous appendicitis. The series included four children of 15 years or under. There were two deaths, both being amongst the appendix cases. One child of 11 died from pneumonia on the fourth day, the necropsy showing a clean peritoneum, although the symptoms had dated from four days before the operation. In one case the patient was four and a half months pregnant but recovered without abortion. One man died on the tenth day after a small secondary abscess had been opened. In the pregnant case no suprapubic tube could be used to drain the pelvis. All the cases were treated with slight modifications of the Murphy method and Mr. Jeans suggested that possibly the continuous administration of salines might act as a vaccine in appendicitic cases by the absorption of solutions of the products of the bacillus coli, but he left this to the vaccinators and the immunisers. -Mr. F. T. Paul mentioned 15 cases under his care during the last year of which 4 had died, 2 from perforated duodenal ulcer. In duodenal cases he recommended closure of the pylorus and gastro-enterostomy if the patient could stand it, as he considered death to arise from secondary leakage. He did not interfere unduly with the peritoneum unless very foul, and he washed it through a double tube. He did not use lumbar drainage, but relied upon a long finely perforated silver tube in the pelvis and packed down to the perforation. He strongly advocated the continuous instillation of saline under the skin by Barnard's method and also the Fowler position, and thought purgatives desirable.

UNITED SERVICES MEDICAL SOCIETY. — The opening meeting of this society was held on Oct. 13th at the Royal Army Medical College, Millbank, S.W., when the President, Surgeon-General A. M. Branfoot, I.M.S. (retired), delivered a short a idress in which the work and progress of the society were reviewed. A plea was made for attention being paid to clinical work, and the subject of neurasthenia—which disease was the cause of a vastamount of inefficiency in the Services—was commended for study.—Lieutenant-Colonel P. J. Freyer, I.M.S. (retired), then read a paper entitled "Total Enucleation of the Enlarged Prostate: Practical Observations on the Operation." The development and anatomy of the prostate with the pathological changes of the enlarged organ were first described and illustrated by sketches. The operation in detail and after-treatment were then given.

664 total enucleations had been done in patients varying in age from 49 to 89 years with an average of 69 years. average weight of the prostates removed was about two and three-quarter ounces, and ranged from half an ounce to 17 ounces. Nearly all the patients were in broken health. The mortality from all causes was 6 per cent. and was steadily decreasing from 10 per cent. in the first hundred cases to 4.24 per cent. in the last two hundred. As a result of the operation a patient regained the power of retaining and passing his urine naturally without the aid of a catheter. Return of symptoms or contraction at the seat of operation leading to stricture and fistula did not occur, and there was no diminution in the sexual power after the operation. A number of prostates which had been removed by Lieutenant-Colonel Freyer were exhibited.—Major C. G. Spencer, R.A.M.C., Lieutenant-Colonel Sir R. Havelock Charles, I.M.S. (retired), and Colonel C. H. Joubert de la Ferté, I.M.S. (retired), took part in the discussion, and the proceedings terminated with a hearty vote of thanks to Lieutenant-Colonel Freyer.

ROCHDALE AND DISTRICT MEDICAL SOCIETY.—A meeting of this society was held on Oct. 21st, Dr. James Melvin, the President, being in the chair.—The President delivered an interesting and instructive address on Faith Healing. Reference was first made to "touching for the King's evil," a practice introduced in the time of Edward the Confessor, and an account was given of the religious ceremonies and formulæ associated with the passing of the Royal hands over the face of the kneeling patient. Wart-charming had been practised from the earliest times, and high authority could be cited for its efficacy. Hypnotism was originated in the eighteenth century by Mesmer and practised by him with great success in Germany. In Paris he reached the height of his fame, patients being so numerous that he delegated his mesmeric functions to a tree. As the result of the findings of a special Government Commission Mesmer was utterly discredited. Next an account of Mrs. Eddy's views as to the non-existence of matter and pain was given. A computation of her probable profits from her own patients and from the training of teachers of her cult amounted to £500,000. Copious quotations were given from Mrs. Eddy's book, "Science and Health," to illustrate her teaching.—An interesting informal discussion followed, several members relating from personal experience their knowledge of the practices of "Christian Scientists."—Dr. Menzies proposed, and Dr. Cox seconded, a vote of thanks to the President for his address, which was carried with acolamation, and Dr. Melvin replied.

ROYAL MEDICAL SOCIETY, EDINBURGH.—The first meeting of the session of this society was held on Oct. 15th, when Dr. F. E. Reynolds read a dissertation on the Wassermann Serum Reaction for the Diagnosis of Syphilis and Parasyphilitic Diseases. At the second meeting held on Oct. 22nd the following gentlemen were elected annual presidents: Dr. D. Maxwell Ross, Dr. R. C. Alexander, Dr. R. C. MacQueen, and Dr. A. Fergus Hewat. Dr. Alexander described two cases in which acute abdominal symptoms had led to laparotomy being performed but in which no cause for the condition could be found.

Another Case of Veronal Poisoning.—At an inquest held recently by Mr. A. Schröder at Paddington it was proved that the deceased, a woman, aged 40 years, had taken rooms in a lodging-house two weeks before her death, and had made statements to her landlady to the effect that she was in straitened circumstances. One day her room door was found to be locked and on its being broken open she was found lying unconscious with an empty bottle near her, which had contained tablets of veronal. The medical evidence showed that death, which followed shortly afterwards, was due to veronal poisoning. The empty bottle had contained 25 tablets, each sold as containing 5 grains of veronal. Dr. Tanner, who gave evidence, called the attention of the jury to the unrestricted sale of tablets such as the deceased had purchased, and they added to their verdict of "suicide while insane" a rider recommending the adding of veronal in the form described to the schedule of poisons.

Rebielus and Notices of Books.

The Cambridge Natural History. Vol. X.: Crustacea and Arachnida. By Geoffrey Smith, M.A., A. E. Shipley, F.R.S., H. Woods, M.A., Cecil Warburton, M.A., and D'Arcy Thompson, C.B. London: Macmillan and Co., Limited. 1909. Pp. 566. Price 17s. net.

This volume completes the Cambridge Natural History, and although it is the last volume to appear it is really No. IV. of the series, which is arranged in an ascending order from the Protozoa up to the Mammals. Nearly 15 years have elapsed since the production of the two earliest volumes, which were published in 1895, and in consequence the authors of the new volume before us are not all of them those to whom the work was originally assigned. delay indeed, to which the editors, Dr. Shipley and Dr. Harmer, now Keeper of Zoology in the Natural History Museum, refer with regret in the preface, was due to the untimely death of one of those at first selected for the important group of the Crustacea. The excellence of the single chapter which the late Professor Weldon left in a fit state for publication shows with what admirable thoroughness that distinguished zoologist had intended to carry out his undertaking. Nevertheless, as a new contributor had to be selected the editors have done as well as they could possibly have done in requesting Mr. Geoffrey Smith of New College, Oxford, to fill the place so prematurely vacated.

Like its predecessors, the present volume is largely technical in treatment, but the paragraphs setting forth details of structure are agreeably tempered by lighter sections dealing with habits; more particularly is this the case with the spiders, whose predaceous lives, singular matrimonial customs, and web-weaving proclivities lend themselves to a treatment of this kind which cannot be meted out to the more stolid and humdrum crustacea, who, moreover, advertise themselves less to the would-be observer. Even in this group Mr. Smith has some interesting facts to tell us of the robber crab, which is now certainly known to climb cocoanut palms in search of its favourite and apparently only food at the present day. At stated seasons the robber crab scurries back to the sea, and its young are as purely marine in their lives as the parents are terrestrial, or, as has been said, even arboreal. The robber crab, which is really not a crab in the stricter sense of that word but an ally of the hermit crab, which seeks shelter, as is well known, for its soft and tender tail in the disused shell of a whelk, grows to so large a size as 1 foot. As these crustaceous animals are not as a rule very large, it is not without interest to note that our common lobster, at least the American specimens of the same, do, according to Mr. Herrick, reach no less a length than 20 inches and a weight of 25 pounds. Both these instances, however, pale before the giant crab of Japan, Macrocheira kämpfferi, which is "supposed to be the largest crustacean in existence, sometimes spanning from outstretched chela to chela as much as 11 feet." The body of this crab is not quite so ungainly as might be inferred from the above quotation, and, even admitting the statement of Herodotus and Mr. H. G. Wells, arthropodous creatures do not ever reach colossal dimensions. The hugest forms appear to belong to the totally extinct Eurypterida, to the consideration of which a chapter is devoted by Mr. Henry Woods. These animals, which reached a length of 6 feet, have been utterly extinct since the Palæozoic epoch. In many respects those great water dwellers of the past resembled the king crabs of to-day, and thus presented an affinity to the scorpion tribe rather than to the crustacea.

The scorpions themselves are a most extraordinary group of animals, in their unaltered persistence upon the globe, as well as in certain details of life. They have existed since Silurian times, and those ancient forms to the eye of even the instructed observer differ but slightly from living scorpions. Mr. Warburton replaces Mr. Woods in taking up the tale of these arachnids, and has plenty to say of the remarkable way of life of what are now entirely terrestrial creatures. As is so often the case with carnivorous animals, as, for example, the serpents, scorpions can maintain life for a long time without any food. They appear to be entirely deaf and to see but indifferently. On the other hand, the tactile sense is acute, and scorpions perform somewhat elaborate antics at the breeding season like their allies the spiders. Mr. Warburton doubts the extreme ferocity with which they have been credited and will have nothing to do with the legend that when thwarted and annoyed they sting themselves to death. A French observer, M. Fabre, established colonies of scorpions in his garden and investigated with thoroughness the ways of life of these arthropods. The wooing of the scorpion is accomplished with resolution and with none of the delicate hesitancy which influences the spider when in quest of a mate. The male scorpion leads the wooed one firmly by the claws to a convenient spot, where he excavates a burrow with one hand, so to speak, while he holds her with the other. But before making this temporary home the two promenade amicably for an hour or more up and down, holding hands the while. Domestic life is, however, but short, for in most cases, Mr. Warburton informs us, the marriage festivities are ended by the female eating up her husband.

Mr. Warburton is also responsible for the section dealing with the spiders, whose anatomy is described with much detail and, like all other parts of this volume, with many and well-selected illustrations. Allied though the spiders are to the scorpions, the venomous bite is effected by the cheliceræ, which are mouth appendages, while in the scorpions the bite is non-venomous, but the poison is expressed through a sting at the end of the tail. The bite of the spider seems to be under the animal's control as to whether it shall be venomous or not. Mr. Warburton thinks that the varying reputation of the tarantula is accounted for by this. The "tarantula" is a spider whose name must in any serious work be written in inverted commas, since the term, like "mosquito," is of general application. Spiders of quite different families have been indifferently called "tarantulas." The panic caused by the appearance of a spider in the retiring chambers of a certain class of lady is not therefore without some justification. Many gruesome tales have been told of the effects of virulent foreign arachnids. A South European lycosid, which has perhaps as much claim as any spider of the district to be the tarantula, bit a mole which died 36 hours later. A bee struck in the right place died at once. Farm labourers have died or been seriously invalided by the bite of a latrodectes. and numerous stories can be got together of the dangerous qualities of many species of spiders.

Space does not allow of further extracts from this entirely readable work, but enough has been said to show the nature of a part of its contents. The more technical details are, as is the case with all the other volumes of this indispensable treatise, in most competent hands, skilled not only in the actual facts dealt with but in their presentment to the reader in an easily assimilable form. The only complaint which we have to make is that the groups are in some cases rather shortly treated. This seems to us to be especially the case with the crustacea, and among the crustacea with the isopods and amphipods. But to cover all the allotted ground in a volume which must at least roughly correspond in size

with foregoing volumes could not have been an easy task, and compression and even omission have proved to be necessary. It may be fairly said, however, that nothing of really first-rate importance has been omitted. The volume is a worthy close to an entirely admirable series; and we offer our congratulations to all concerned in its production.

A Text-book of Special Pathology for the Use of Students and Practitioners. By J. MARTIN BRATTIE, M.A. N.Z., M.D. Edin., Professor of Pathology and Bacteriology, University of Sheffield; Honorary Pathologist to the Sheffield Royal Infirmary and Royal Hospital; and W. E. CARNEGIE DICKSON, M.D. Edin., B.Sc., F.R.C.P. Edin., Lecturer on Pathological Bacteriology and Senior Assistant to the Professor of Pathology in the University of Edinburgh; Assistant Pathologist, Royal Infirmary, Edinburgh. With 191 illustrations and two coloured plates from original preparations. London: Rebman and Co. 1909. Pp. 599. Price 17s. 6d. net.

THIS book forms a companion volume to the text-book of general pathology by the same authors, of which we have recently published a review.\(^1\) Like its predecessor, it aims at presenting the teaching of the Edinburgh school and the authors acknowledge their indebtedness to Professor W. S. Greenfield, at whose suggestion the work was undertaken, for placing the notes of his lectures at their disposal and for his cooperation.

The book is divided into nine chapters, in which the pathological changes occurring in the various systems of the body are categorically considered. The general arrangement of the subject matter is convenient and easy of reference, while the classification of the lesions of each organ or system is good. The descriptions given are not exhaustive, but the salient features are clearly set forth and the principal objects of note are indicated in thicker type. The illustrations, which are numerous, are reproductions of photographs of actual specimens and are well executed, while the good quality of the paper used in the book renders them unusually clear and distinct. There are two coloured plates representing the various forms of normal and abnormal blood corpuscles. They are faithful reproductions of stained specimens, and they leave nothing to be desired in the matter of accuracy, while the descriptive notes are so arranged as to be clear and definite.

Diseases of the circulatory system are first considered, the morbid changes in the heart being succinctly described. In connexion with diseases of blood-vessels a clear account is given of atheroma, this term being taken to include arteriosclerosis and endarteritis deformans as well as the condition to which it is sometimes restricted. The second chapter. which treats of diseases of the blood and blood-forming organs, is worthy of special note, and contains a useful study of the changes in the bone marrow in disease. which is reproduced from a paper published by one of the The various cells found in the marrow are anthors.2 classified, and the reactions induced in this tissue by disease are divided into leucoblastic and erythroblastic, the latter being of either normoblastic or megaloblastic type in conformity with the Ehrlich terminology. A clearly written and up-to-date account is given of lymphadenoma or Hodgkin's disease, incorporating the work of Longcope, whose conclusions are given.

The third chapter is devoted to diseases of the respiratory system, and among these tuberculous disease of the lungs and pleura is considered at some length. The authors believe with Ravenel that the commonest mode of entry in the human subject, except in young children, is by way of

¹ THE LANCET, August 21st, 1909, p. 533.

² W. B. Carnegie Dickson in International Clinics, vol. Series xvii., 1907.

They mention the recent work in connexion with the intestinal source of infection. Their account of the lesions in pulmonary tuberculosis is clear, and their classification of the varieties is convenient. This section is illustrated by numerous reproductions of photographs of tuberculous lungs.

Diseases of the digestive system are dealt with in the next chapter, and although all the important lesions are mentioned and briefly described, the accounts given often err on the side of brevity. The diseases of the ductless glands are next considered, including the thyroid, thymus, pituitary and suprarenals. The sixth chapter includes a general description of the diseases of the genito-urinary system and of the mammary gland. Abnormal conditions of the kidneys are described at some length, and the descriptions are clear and to the point. Diseases of the nervous system are briefly described, and numerous reproductions of photographs of specimens prepared by the Pal-Weigert method are given. Some of the descriptions might here also be lengthened with advantage. The concluding chapter deals with diseases of the bones and joints. The account given of rickets is good and is well illustrated. An unusually complete index is added, rendering reference easy and convenient.

The book should be a useful work for students as an introduction to special pathology and as a companion to systematic works on medicine.

Clinical Studies. A Quarterly Journal of Clinical Medicine. By BYROM BRAMWELL, M.D. Edin., F.R.C.P. Edin., F.R.S. Edin., Physician to the Edinburgh Royal Infirmary; Lecturer on Clinical Medicine in the School of the Royal Colleges, Edinburgh. Vol. VII. Edinburgh: R. and R. Clark, Limited. 1909. Pp. 395.

In publishing the seventh volume of "Clinical Studies" Dr. Bramwell again records a number of interesting cases which were seen at the "Wednesday cliniques." Amongst these was a peculiar form of lead poisoning, with tremors and marked loss of vision, both for white and for colours, without any changes being apparent in the fundus oculi. The diagnosis rested between plumbism and intracranial tumour, but the occupation of the patient (employment in a paint manufactory), constipation, the state of the gums, attacks of colic, together with a fine muscular tremor in the right hand and arm were in favour of the former condition. This opinion was confirmed by a rapid recovery under sulphate of magnesia and iodide of potassium. Another case was that of spleno-medullary leukæmia with unilateral optic neuritis in which there was a rapid drop in the number of white corpuscles-440,000 to 10,400 per cubic millimetre. The case proved fatal. A particularly rare and interesting case was one of chronic pneumonia due to the pressure of a small aneurysm on the left bronchus. At the necropsy the left lung was found partially collapsed; it was of small size and lay at the posterior part of the cavity. At the end of the arch of the aorta there was a small aneurysm of about the size of a walnut projecting to the inner side and coming into contact with the main bronchus of the left lung, just below its point of origin from the traches. On microscopical examination of the lung the pleura was found to be much thickened and the interlobular septa and general framework showed well-marked fibrous thickening; the walls of the air vesicles also exhibited a similar though less-marked condition. The air-cells were filled up with catarrhal cells mixed with a few leucocytes and granular matter. places here and there were patches of semi-purulent material with interstitial thickening around—a chronic suppurative condition in relation to the small bronchi.

diagnostic and therapeutic value of lumbar puncture. enumerates the circumstances in which this procedure has been found of use, especially drawing attention to the differential diagnosis of the various forms of meningitis, soenabling obscure cases of cerebro-spinal fever to be recognised, in which isolation and serum treatment are indicated. An analysis is given of 42 cases of progressive muscular atrophy and also of 42 cases of pseudo-hypertrophic paralysis and myopathic muscular atrophy.

There is much that is interesting in this volume, the record of cases being especially valuable.

A Text-Book of Mental Diseases. By EUGENIO TANEL. Authorised translation from the Italian by W. FORD ROBERTSON, M.D. Edin., and T. C. MACKENZIE, M.D. London: Rebman, Limited. 1909. Pp. 820. Price 24s. net.

In his preface Professor Tanzi sets forth that he has endeavoured in this work, in due proportion, to reflect two tendencies that underlie modern psychiatry. On the one hand, there is the man who wants to know what psychiatry is; and on the other, the idealist who strives to ascertain what it will become. The one requires facts, and only those that are certain, harmonious, and of general practical value; the other is interested in hypotheses, in the direction that is being taken by an advancing science, in its past and in its future. It would appear that modern critics are indulgent to the man who collects facts uncritically, and unconsciously alters, exaggerates, and invents them, whilst they are implacable to him who guesses at the truth and naturally leaves his hypotheses undemonstrated, however rational, useful, and probable they may be. There are, nevertheless, alleged facts that are illusory and hypotheses that become verified. It would be better if there were more rigour in the examination of facts and less precipitation in the condemnation of hypotheses. This due proportion Professor Tanzi has preserved in a masterly fashion, and we know few works in which facts and hypotheses, placed alongside each other, are more judiciously blended, or in which the facts and hypotheses are more philosophically subjected to an impartial criticism.

As is now customary in psychiatrical works, the first few chapters are devoted to the general anatomical and physiological data of the normal and abnormal processes of mind. The account is good and adequate and not too long for a work which is not one of anatomy or physiology. In succeeding chapters sensibility, ideation, memory, the sentiments and the movements and other external reactions are considered, and it is with pleasure that we note that the physiology and pathology of these various conditions are placed in juxtaposition in the same chapters and are not divorced, as is too often the case, by being placed by themselves in different parts of the book. As regards our knowledge of structure, the author is of opinion that the facts of pathological anatomy, now definitely ascertained in cases of mental disease, considered in the light of experimental pathology, enable us to say whether certain lesions are diffuse or circumscribed, reparable or irreparable, recent or congenital, and hence also to connect them with some of the symptoms manifested during life, although they are very far from serving to reveal the psychical phenomena to which they correspond. We are enabled to arrive at a synthesis which makes it possible to regard a number of psychoses from a common point of view, and to refer their stages and clinical features to a definite series of material processes.

Professor Tanzi's theory as to the mechanism of hallucinations is interesting. The sensorial centres of vision are Dr. Edwin Bramwell is responsible for an article on the a looking-glass, those of hearing a resonator, those of

outaneous sensibility an instrument for instantaneous signalling, and nothing more. The mnemonic representations of external phenomena are built up in other centres in the form of symbols, and these are direct symbols. From the centres of representation the direct symbols can pass to higher centres in order to form more general and more abstract conceptions, and these are symbols of symbols. The sensorial centres are of themselves unable to give any complete images, but can only reflect them. In normal conditions they only reflect the external objects that actually present themselves. To reflect also the mental images of objects re-awakened within us they must be in pathological conditions, or there must be at least unusual conditions, such as those of sleep. In order to give a satisfactory explanation of all varieties of hallucinations it is sufficient to suppose that the homolateral and contralateral paths that pass from the centres of sensation to the centre of representation acquire the power, which they never possess in normal conditions, of allowing impulses to travel in the reverse direction. A hallucination may be considered as taking origin as an idea or symbol but instead of forming associations with other ideas it flows back, either by the same homolateral and contralateral fibres by which it came or in some other way vet to be determined, to the sensorial centres from which it proceeded when it was of the nature of a sensation. Thus it becomes what it originally was, a sensation. It is, however, a sensation of an unusual character, that is, of a pathological character. This power of retrogression forms the special morbid character that determines the individuality of hallucination both as a psychological phenomenon and as a clinical symptom. The sensorial centres are importers in relation to external objects, but exporters in relation to the internal demain of transcortical thought. If owing to a pathelogical inversion they import from within it is natural that they should react in the only way in which it is possible for them to react—that is, by the production of sensorial images. In whatever way the pathological reflux may be effected it is important to recognise that a hallucination consists exactly in this reflux. Thus understood, the physicnathological process of hallucination acquires features that are altogether special and befitting the indisputable fact of its unique character. It is no longer simply an extreme intensification of a representational image but the morbid degradation of a representation that was once a sensation, and which, through being broken up under abnormal conditions, becomes again a sensation.

In mental pathology the question of classification is more complicated than in ordinary pathology. The diseases with which it has to do are less distinct. Apart from a few forms, such as progressive paralysis, alcoholism, and infantile cerebroplegia, only syndromes are known, and the same syndrome may be the outward expression of the most diverse diseases. The conception of disease implies a constant and definite, or at least approximate, correspondence between the symptoms and the organic morbid processes. Owing to the absence of such correspondence or doubt as to its existence the phenomena of insanity cannot all be included in a single view. Each person sees them from his own standpoint, and classifications are consequently either fallacious or incomplete. There is, however, amongst the later authorities a distinct tendency towards greater uniformity founded upon the rational classification devised by Kraepelin. Professor Tanzi's classification has much to be said for it, and yet further simplifies the grouping of morbid entities and syndromes.

The translation appears to us to be faithful, while the English in which it is couched is so good that it has the merit of concealing the fact that the work was originally in

a foreign language. The work itself we regard as one of the best presentations of the science of psychiatry with which we are acquainted.

LIBRARY TABLE.

Diseases of Women. By J. BLAND-SUTTON, F.R.C.S. Eng., and ARTHUR E. GILES, M.D., B.Sc. Lond., F.R.C.S. Edin. Sixth edition. With 123 illustrations. London: Rebman, Limited. 1909. Pp. 554. Price 11s. net.—The appearance of the sixth edition of this well-known handbook shows that it has met with appreciation on the part of students and practitioners. The authors have made a considerable number of additions and have added several new sections. The first of these deals somewhat sketchily with injuries to the uterus, both gynæcological and obstetrical. Chapters have also been added on fibrosis uteri and adenomyomata of the uterus. By the former term the authors mean the condition of the uterus often associated with severe menorrhagia in which there is a marked overgrowth of the connective tissue in the wall of the uterus, the "arterio-sclerosis of the uterus" or "chronic metritis" of other authors. This change undoubtedly occurs in the uteri of all women after the menopause, but when it occurs prematurely and to an excessive degree it may give rise to very intractable hæmorrhage. The authors believe that it is produced by previous septic endometritis, sometimes puerperal in origin and sometimes the result of gonorrhœa. They maintain that the only treatment of any avail is hysterectomy, and for severe cases no doubt this is the correct treatment. Really severe cases of this disease are very rare, and Mr. Bland-Sutton has had exceptional experience since he has performed hysterectomy for fibrosis of the uterus no less than 67 times. It is a pity, therefore, that the description of the pathology is not given a little more fully; it would have been interesting to have had a microphotograph of the condition found in these cases with the elastic tissue shown by a differential stain. The account of adenomyomata of the uterus is short but good, although the authors express no opinion as to the origin of the glandular spaces and we are left ignorant as to which view they adopt. In consequence of the frequency with which the radical operation of total abdominal hysterectomy is being performed at the present day, the authors have devoted a chapter to injuries of the ureters. The description of Wertheim's operation itself would appear to have been written with little or no experience of the procedure, or otherwise the most difficult and important step of the operation, the wide removal of the cellular tissue at the base of the broad ligaments, would not be dismissed in such a description as, "The two layers of the parametrium are taken off as close as possible to the pelvic wall." Not a word is said about the use of Wertheim's clamps, one of the most important of the improvements introduced by him in his method of carrying out the operation, and one upon which he lays special stress in his latest writings on the subject. The statement that no trustworthy returns concerning the remote results are at present available is also only correct if it is intended to apply to the results of British operators only. Detailed results of Wertheim's first 120 cases in which five years had elapsed since the date of the operation, showing 51 cases, or 42 per cent., of complete freedom from recurrence. were published by Wertheim last year.

Dictionary of Ophthalmic Terms, with Supplement. By EDWARD MAGENNIS, M.D. R.U.I., D.P.H. Bristol: John Wright and Sons; London: Simpkin, Marshall, and Co. 1909. Pp. 67. Price 2s. 6d. net.—In the preface it is stated that many of the terms will "not be found in the ordinary medical dictionary." There are a good many medical dictionaries on the market, and it is not obvious

which is the "ordinary one," but if it has omitted some of the errors in Dr. Magennis's catalogue it is to the credit of the ordinary dictionary. To take two pages only: "canities" is not "a decoloration of the lashes"—it means a patchy decoloration of the hair anywhere on the head or body; similarly "chromidrosis" is not confined to the eyelids. By what perversion of Latin is the "nucleus caudatus" dubbed the "caudatum," and the "nucleus lenticularis" (unless the "ansa lenticularis" is meant), called the "lenticularis" tout court? The "caudatum" (sio) is described as "a ganglion or free ring of grey matter circling round the lenticularis of the brain." The Latin is incorrect, the description is misleading, and the connexion of the subject with ophthalmic terms is obscure. We cannot conscientiously commend this dictionary to our readers.

The Pocket Medical Dictionary. Edited by W. A. NEWMAN DORLAND, A.M., M.D. Sixth edition. London and Philadelphia: W. B. Saunders Company. 1909. Pp. 598. Price 5s. net.—It would be idle to question the utility of a work which has seen so many editions in so short a time. Many persons obviously require such a dictionary, and to those many this little volume must commend itself on account of its compact, neat form and its excellent paper and type. Tiny and portable as it is, the book is very full and complete-in fact, it is almost too complete in its inclusion of words not strictly medical but dealing with collateral sciences. It would be impossible to compile such a collection of definitions without errors, and equally impossible to enumerate many of such errors within the space at our command. To select an example at random, the term "Charcot's disease" is usually applied to the synovial destruction in locomotor ataxia and not to insular sclerosis. Charcot in his admirable historical note on the latter condition lays great stress on the fact that from 1835 onwards Cruveilhier, Carswell, Turk, and many others had described it before M. Vulpian and he himself placed new examples on record in 1862.

Ann Veronica: a Modern Love Story. By H. G. WELLS. London: T. Fisher Unwin. 1909. Pp. 352. Price 6s.-We have travelled far from the day, almost 50 years ago, when Mrs. Jolly Newboy, of Pocklington Gardens, horrified that faithful chronicler of contemporary manners, Mr. M. A. Titmarsh, by asking her husband for "The Chubb Key." The points of difference between the young woman of Mrs. Newboy's date and Mr. Wells's latest heroine are almost inconceivable. But Mr. Wells's careful study has resulted in a novel which is extraordinarily clever but which is in places deliberately unpleasant. The honesty of purpose which has inspired the author is transparent, but surely it would have been possible to produce the necessary impressions in a subtler manner—possible, at any rate, for so really brilliant a writer as Mr. Wells. Ann Veronica is a young woman with views, but by no means a fool. Her struggles, her circumscribed home life, the way in which she just missed being a lady, her acquaintances the Widgetts and the various weird persons with whom she came into contact when she went out into the world "on her own" are drawn with extraordinary skill. So are all the scenes at the Imperial College, where she studied biology. Mr. Kipling, we recollect, made two of his characters who were engaged (the man was in the Indian Canal Department) talk of "barrage and aprons and waste water" which, as their host remarked, was "their style of spooning." So Ann Veronica first knew that she was in love with Capes over "a ribbon of sections of the developing salamander." Perhaps the best part of the book is the description of all the people "in the van" who were trying to reconstruct things in general. Thus, "The Goopes were the oddest little couple conceivable, following a fruitarian

career upon an upper floor in Theobald's Road. They were childless and servantless, and they had reduced simple living to the finest of fine arts. Mr. Goopes, Ann Veronica gathered, was a mathematical tutor and visited schools, and his wife wrote a weekly column in New Ideas upon vegetarian cookery, vivisection, degeneration, the lacteal secretion, appendicitis and the Higher Thought generally, and assisted in the management of a fruit shop in the Tottenham Court Road. Their very furniture had mysteriously a high browed quality, and Mr. Goopes when at home dressed simply in a pyjama shaped suit of canvas sacking tied with brown ribbons, while his wife wore a purple djibbah with a richly embroidered yoke." Another delightful character, Miss Miniver, expressed herself thus: "When I am leading a true life, a pure and simple life, free of all stimulants and excitements, I think—I think—oh! with pelluoid clearness; but if I so much as take a mouthful of meat—or anything the mirror is all blurred." "Ann Veronica" will not commend Mr. Wells to any leaders of the ridiculous side of modern progressive movements, but the book should be read by all those who are striving towards an ideal for which the world is not ready, however desirable it may be. It should convince some of them that although they hold their views in all honesty those views may be unsound.

JOURNALS AND MAGAZINES.

The Edinburgh Medical Journal.—The October issue is a Special Educational Number, containing details of the curriculum at the Edinburgh Medical School, and a section on Medical Education in Scotland generally. Dr. Alexander James writes on the Infective Element in Consumption and seems inclined to believe that allies of the tubercle bacillus, such as the smegma bacillus and the grass bacillus, may be capable of assuming pathogenic rôles. Dr. H. A. Lediard discusses removal of the normal appendix as a routine measure comparable with circumcision. We trust that his views in favour of this procedure may not find general acceptance. Dr. G. H. Melville Dunlop contributes a brief paper on the Treatment of Constipation in Children and incidentally urges the advisability of giving them a more liberal allowance of cold water to drink than they usually receive.

The Caledonian Medical Journal.—The October number of this magazine commemorates the annual meeting of the Caledonian Medical Society at Lancaster in September last. The presidential address, delivered by Dr. David Blair, deals with some neglected problems in race preservation, among them the frequency of marriage between the unfit and degenerate, and the tendency to comparatively sterile unions between the more cultivated and provident members of society. Sir Dyce Duckworth sketches some incidents in the life of an old Stonehaven worthy, his own grandfather, William Nicol; and articles of literary rather than medical interest are contributed by Dr. H. McCalman on "The '15 and '45 in Lancaster," and by Dr. Lachlan Grant on "Books and Reading."

The Manchester Medical Review.—The August issue of this journal, which is now before us, contains an interesting account by Dr. Alexander Fraser of a visit to Lourdes and of the surroundings and features of this famous place of pilgrimage. A letter from Dr. J. H. Taylor reviews the unsatisfactory state of things prevailing at the Hope Hospital, Salford, which has led to an absence of medical candidates for the post of resident medical officer. More directly scientific matter is afforded in a paper by Dr. N. C. Haring on Operations on the Nasal Septum, in which the various procedures available are reviewed and the submucous operation is recommended.

Rew Inbentions.

A NEW ELECTRIC RECTIFIER.

WE have had an opportunity of examining a new instrument for rectifying alternating currents into uni-directional impulses. It is supplied by the Premier Ampero Electric Co., of Premier House, Dover-street, London, W., and will be found a most useful and efficient apparatus for charging accumulators, such as are used for motor ignition and various kinds of medical work, in those districts where the current from the main is an alternating one. The principle upon which it is constructed is somewhat the same as that devised by Dr. Batten some years ago, but it is more efficient and rather more silent in action. A great feature of this instrument is that the point on the pressure curve of the alternating supply, where the current is picked up and cut off, is adjustable and can be arranged to take place at the voltage of the cells. At such times as the charging current is at a lower voltage than that of the cells undergoing charge the circuit is open and no current can pass back through the rectifier. When properly directed which is adjusted, which is a very simple procedure, there is no visible sparking at the contacts. On our visit we saw the instrument converting an 85-cycle alternating current into direct current and charging some ignition cells, and also running a small direct current shunt-wound electric motor, which latter, as is well known, will not work with an alternating current. If the main supply should fail from any cause the instrument cuts itself out of circuit automatically. It will work on any periodicity in ordinary use, starts and runs on any load, requires no attention, and is efficient in any position. The makers claim that the instrument will go for six hours a day for six months without attention, and then all that is needed is a new set of platinum contacts at a trifling cost. The directions to be followed are extremely simple, and altogether we have seen no better instrument for its purpose.

THE LONDON SCHOOL OF TROPICAL MEDICINE.

THE winter session of the London School of Tropical Medicine was opened on Tuesday, Oct. 26th, in the presence of a representative company of officials and scientific workers by an eloquent address from Professor W. Osler, who appealed, under the title of "The Nation and the Tropics," for the adequate endowment by this country of tropical research.

Mr. WHITELAW REID, the American Ambassador, presided over the meeting.

Professor Osler's brilliant address, which will shortly appear in full in our columns, showed conclusively the need for a central scheme by means of which the various expeditions sent out as Commissions of the Government, of the Royal Society, or of universities could be all kept in touch with each other and with any later work in similar directions. He considered that the necessary organisation, though it would demand £2,000,000 for its initiation and support, for the equipment of laboratories and libraries, and for the payment of professorial salaries, was quite within the range of possibility.

The AMERICAN AMBASSADOR pointed out that the pursuit of tropical medicine was the only rational course of a nation possessed of tropical dependencies. He outlined the conditions met with and dealt with successfully both in Cuba and Panama, and said that these were instances where the study of tropical medicine had made possible national progress.

Professor W. J. R. SIMPSON proposed a vote of thanks to Professor Osler, which was seconded by Professor RONALD Ross.

Mr. NAIRNE, chairman of the Seamen's Hospital Society, proposed a vote of thanks to the Chairman, which was seconded by Sir PATRICK MANSON and briefly replied to by the AMERICAN AMBASSADOR.

THE ANNUAL DINNER.

The annual dinner of the London School of Tropical Medicine was held in the evening at the Savoy Hotel, Strand, Dr. A. G. Bagshawe, Director of the Sleeping Sickness Bureau of the Royal Society, presiding. A large company was present at the dinner, and the proceedings throughout testified to the great development of the work of the school

and the necessity there was for some proper endowment. The school has had admirable results, has passed 1000 of its students into all parts of the Empire equipped to fight diseases of the deadliest sort, and has a claim, not only upon the city at whose water-gate it is established, but upon the whole Empire. This claim has not yet been recognised at all, but it is hoped that the publicity given to the good record of the school will change the position of affairs. It should be mentioned that Lord Sheffield (Lord Stanley of Alderley) is defraying the cost of an expedition to Fiji this year out of a fund with which he has endowed the school in memory of his son, the late Honourable Edward Stanley, the Assistant Commissioner of Northern Nigeria, who died last year at the early age of 30 from hepatic abscess following dysentery. But this is an individual instance of generosity.

Dr. BAGSHAWE took the chair at the dinner, supported by Lord Sheffield and Principal H. A. Miers, and among others present were Sir Patrick Manson, Sir William Collins, Professor Ronald Ross, Mr. H. J. Read of the Colonial Office, Dr. F. M. Sandwith, Professor Simpson, Sir Francis Lovell, Sir William Treacher, and Mr. P. T. Michelli (secretary). After the loyal toasts had been duly honoured the CHAIRMAN proposed the toast of "The School" in an interesting résumé of the development of tropical medicine.

Sir Patrick Manson followed with a eulogy of Professor Osler, "the orator of the day," as lecturer, philosopher, and guide, to which toast Principal MIERS, in the unavoidable absence of Professor Osler, replied with some witty remarks which were very well received. But Lord SHEFFIELD made the speech of the evening in response to the toast of "The Guests." He placed the claims of tropical medicine before his hearers from the utilitarian and humanitarian side alike, and he urged upon all engaged in the work the necessity of bringing their just demands for endowment loudly and frequently before those in authority. Government officials, he pointed out, were men like themselves, anxious to be right, anxious to do right, and liable to make mistakes in circumstances which they did not understand. It was necessary to make those in charge of the business of the country understand that it is their duty, their common economical duty, to the Empire to see that the servants of the Empire in its far dependencies receive all the aid in their work and all the chances of health preservation which modern scientific methods can afford. Lord Sheffield's speech was punctuated throughout with the applause of the company, and was an effective exposition of the aims of tropical medicine.

The proceedings closed with the toast of "The Chairman," ingeniously given by Mr. CANTLIE and responded to by Dr. BAGSHAWE in a brief sentence.

THE ROYAL DENTAL HOSPITAL. — The Royal Dental Hospital and London School of Dental Surgery held a conversazione at the Royal Institute Galleries on the evening of Oct. 20th. Sir Victor Horsley distributed the prizes and eulogised the spirit of unity existing between medical men and dentists. He also spoke of the administration of anæsthetics by dentists, declaring that all dental students should be instructed therein. He suggested that they might be taught the administration of anæsthetics other than nitrous oxides in general hospitals. The chief prizes were Scholarship, Mr. H. D. Stephens; The Saunders Scholarship, Mr. W. L. Jackson; Alfred Woodhouse Scholarship, Mr. E. L. Fickling; Robert Woodhouse Prize, Mr. G. J. Harborow; and Ash Prize, Mr. C. G. Colyer. After the distribution, Mr. E. T. Reed delivered a lecture, illustrated by lantern slides, on Caricature in and out of Parliament. Various scientific exhibits were made by Mr. Richard Kerr, F.R.A.S., Mr. A. Hopewell-Smith, Mr. S. Henson, Messrs. Newton and Co., Messrs. Spencer and Sons, Messrs. Watkins and Doncaster, Messrs. J. R. Gregory and Co., and Messrs. Baird and Tatlock.—The annual dinner of the staff and past and present students will be held on Saturday, Nov. 20th, at the Hôtel Métropole (Whitehall Rooms), under the presidency of Mr. C. F. Rilot. Gentlemen either now or formerly connected with the hospital or medical school who may through inadvertence not have received special notice and who desire to be present are requested to communicate with the Dean at the Royal Dental Hospital, 32, Leicester-square, London.

THE LANCET.

LONDON: SATURDAY, OCTOBER 30, 1909.

Recent Advances in our Knowledge of Sleeping Sickness.

WE published last week an admirable address on the Recent Advances in our Knowledge of Sleeping Sickness, which was delivered before the Society of Tropical Medicine and Hygiene by Dr. ARTHUR G. BAGSHAWE, Director of the Sleeping Sickness Bureau of the Royal Society. In that address Dr. BAGSHAWE carefully limited himself to the consideration of work done during the past 12 months, especially such as had an immediate bearing upon prevention or cure, and his practical remarks on the administration of the arsanilates enable us to form a better idea than we have had before of the fatality of the disease.

We have now received the report of the German Commission on Sleeping Sickness, appointed in 1906 to proceed to East Africa with a subsidy from Imperial funds to cover the cost of the expedition. This report may well be considered in connexion with Dr. BAGSHAWE'S address, to which it supplies a very interesting back-Professor R. Koch, who had already had previous acquaintance with the disease while engaged in other work in Africa, was chosen as leader of the expedition, and with him were associated two colleagues-Professor KLEINE, of the Royal Prussian Institute for Infectious Diseases at Berlin, and Staff-Surgeon KUDICKE, of the East African Protectorate troops. Later, Professor BECK, of the German Imperial Health Department, was added to the Commission, as also was Dr. PANSE, of the German East African Government Medical Service. The expedition arrived in Africa in May, 1906, and returned to Europe in October, 1907. Before completion of the work Dr. PANSE at his own request left the Commission, and we regret to state that he died shortly afterwards. During the time, about two years, which had necessarily to be spent in preparing for publication the material collected by the expedition considerable advances had been made in the knowledge of sleeping sickness, and many points which were in doubt at the time when the German Commission were completing their observations have since been explained fully by the researches of other experts. In spite of this the report is a most interesting and valuable work; the investigations were carried out with characteristic diligence and zeal and with close attention to scientific details. The volume is profusely illustrated and contains about 100 reproduced photographs (most of which were taken by Professor KLEINE), several maps, coloured plates, and a considerable number of charts. It deals separately with the etiology of the disease, its diagnosis, clinical features, treatment, and prophylaxis. In the preface Professor Koch disclaims any idea of the book being regarded

as a monograph on sleeping sickness. Some important points, indeed, have not been dealt with, since the Commission, as is stated, had no special opportunities for inquiring into them. A part of the time of the expedition was spent in the study of the disease in British territory, more particularly in Uganda. Some of the islands in the great Victoria Nyanza afforded exceptionally favourable conditions for carrying out etiological investigations. On some of the smaller uninhabited islands of the Sese group it appears that although human beings are entirely absent, yet there are plenty of water-fowl, crocodiles, lizards, and snakes. Glossina palpalis is also present in overwhelming numbers. As no human blood is available for the food of the female insects it was expected that the glossinse would seek their nourish. ment by biting the wild birds. But, contrary to expectation, it was found that the blood which was present in the stomach and intestines of captured glossins was almost invariably that of crocodiles, and in this blood in some instances trypanosomes were found. The latter were of four types, none of which, however, closely resembled the trypanosoma gambiense. Occasionally on careful examination trypanosomes were found in the salivary glands of the insects, and this circumstance was regarded as supporting the view that a developmental cycle of the parasite had taken place in the body of the glossina. To answer the question whether or not man was the only host of the trypanosoma gambiense, many other animals were examined, including cattle, goats, sheep, dogs, monkeys, wild pigs, hippopotami, and antelopes. Most of these animals are found on the shores of the Victoria Nyanza and most of them suffer from the onslaughts of blood-sucking flies like the glossina. In none of these animals, save in a single monkey, were any trypanosomes found by the Commission. From this observation it was concluded that these animals, excepting perhaps the monkey and the dog, were insusceptible to this form of trypanosomiasis. Large numbers of wild birds were also examined, including cormorants, herons, kingfishers, wild geese, weaver birds, and the like, but without result, except that in a rhinoceros bird some trypanosomes, not resembling the trypanosoma gambiense, were discovered. Fishes were also investigated but without finding traces of any trypanosomes in their blood. The inquiry was then extended to reptiles, including turtles, lizards, and crocodiles, and in the blood of these trypanosomes were not infrequently found. Of 12 full-grown adult crocodiles which were very carefully examined trypanosomes were discovered in four, the parasites, however, not being present in any great number. It cannot be taken as proved that these trypanosomes were related to trypanosoms gambiense, but nevertheless Professor Koch regards these reptiles as a grave source of danger in the spread of sleeping sickness since they probably serve upon occasion as hosts for the specific parasite. Experiments to inoculate artificially young crocodiles under four years of age with the trypanosoma gambiense were entirely unsuccessful. The female crocodile lays from 60 to 70 eggs in her nest. Professor Koch himself found 40 of these nests containing an aggregate of 2000 eggs, which he destroyed or used for scientific purposes. He recommends that the natives should be paid a reward

¹ Bericht über die Tätigkeit der zur Erforschung der Schlafkrankheit im Jahre 1906-07 nach Ostafrika entsandten Kommission, Berlin, 1909, Julius Springer.

for seeking out these nests and for destroying the eggs and that the carcasses of lambs or kids into which arsenic had been put should be used as poisoned baits to kill the adult crecodiles. It is concluded that the glossina prefers human blood for its food, but when that is not available it falls back upon the blood of the crocodile for its nourishment, at least in the region of the Victoria Nyanza.

Other measures recommended by the German Commission are already familiar to our readers, including the cutting down of bushes and undergrowth close to the banks of streams and lakes to destroy the haunts of the glossina, particularly in the vicinity of fords, ferries, and places from which the natives draw water. The collecting of rubber in these regions should be suspended according to the German Commission, and boating and fishing on the Victoria Nyanza should be forbidden to the natives for the present; the villages should be removed from the localities infested by glossina to fly-free areas back from the lake. Early treatment by atoxyl is strongly urged by the German Commission, the dose to be repeated every tenth day, not only with the object of curing the disease, but also to keep the trypanosomes out of the circulation and thus avoid infection of fresh glossinse. The limitations of atoxyl and soamin indicated by Dr. BAGSHAWE must here be borne in mind, for their efficacy in any but the earliest stage in the disease is doubted by Dr. BAGSHAWE as a result of the examinations of the most recent work. Early treatment requires early diagnosis of the disease, and for this purpose, after careful consideration of the value respectively of examination of gland juice, cerebro-spinal fluid, and blood, the German Commission recommends blood examination as the safest, simplest, and speediest method of arriving at a definite diagnosis, and Dr. BAGSHAWE says in so many words that the diagnosis cannot be established unless the trypanosome is found in one or other of the body To secure systematic treatment by atoxyl and for other reasons the German Commission considers it advisable to have as many sufferers as possible collected in camps located outside the fly area, and in order to prevent the spread of aleeping sickness into adjoining territories international regulations for restricting the movements of natives and establishing examination stations on the frontiers should be carried out. In this way any infected natives endeavouring to escape could be detained and transferred to a camp for treatment and observation. These are matters to which our Colonial Office must already have had its attention drawn, and they illustrate once again the fact that scientific medicine is bound to become in the future the great argument for international amity.

Hair-balls.

MASSES of hair are not very rarely found in the stomach and intestines of animals, though they are unusual in the human gastro-intestinal tract. The habit of licking the surface of the skin, so common and so salutary in many animals, is mainly responsible for these collections of hair, whose formation is also greatly facilitated by the character of the hairs of many animals which are rough on the surface from the projections of the superficial cells. When hairs such as

these are rubbed or beaten together they become matted-in other words, they "felt"-for the projecting teeth interlock, and this felting process takes place much more readily with the hairs of some animals than with those of others, the difference of behaviour being entirely due to the difference in the surface of the hair. In human hair the external roughness, so apt for the production of felting, is not present, but hair-balls are occasionally found in human stomachs, and their presence must enter into the category of possibilities in making an exhaustive diagnosis. A valuable paper on this rare condition is contained in the issue of the Journal of the American Medical Association for August 21st, by Dr. W. W. BUTTERWORTH of New Orleans. In this article the observer records a case which was under his own care, and the details may be usefully recapitulated. The patient was a girl, eight years old. She had been sickly for the first two years of her life, but later she had been in better health, though she was pale and ansemic. Rather more than a year before her death she became very weak and had frequent vomiting, while the stools contained much mucus. For several months prior to this last illness she was known to be in the habit of eating sand, a fact which might have caused her immediate relations more anxiety if they had realised the serious omen of this sort of perverted appetite. She was taken ill with abdominal pain near the end of October, 1908, and a firm, crescent-shaped swelling in the epigastric region was found by Dr. N. W. FOUNTAIN. The temperature was 104° F., the respirations were 40, and the pulse was 148 per minute. The temperature fell after free catharsis. On the fifth day the blood showed tertian malarial organisms, and in the stools many uncinaria ova were found. She was treated with quinine and phenacetin. She was admitted into hospital a few days later, but the general condition was so bad that an exploratory incision was not considered advisable. The temperature remained between 100° and 102° F., at times she had paroxysmal abdominal pain, and she grew weaker and died on the twenty-seventh day of her illness. At the necropsy the stomach was found to contain a firm mass of hair moulded to the shape of the interior; many of the hairs of which it consisted were 15 inches long. The mucous membrane of the stomach was normal except near the pylorus, where there was a chronic ulcer one inch in diameter.

This story furnishes a good example of the symptoms produced by hair-ball in the human body, though complications in the form of malaria obscured the diagnosis. Moreover, the patient, though known to swallow sand, was not known to swallow hair. The pathological accident is much more common in girls and women than in men, and of the 42 recorded cases which Dr. BUTTERWORTH has succeeded in collecting 39 were females; this preponderance is doubtless due to the fact that girls wear their hair long and it is therefore much easier for them than it is for boys to get the ends of the hair into the mouth. The taste once acquired may persist for years, and the hair may be torn from the scalp and swallowed, but at first it is probable that only the tips of the hairs are bitten off. In the majority of cases the practice appears to commence in girlhood, and it is sometimes associated, but by no means

always, with the practice of eating sand and dirt-"pica," as it used to be called. Human hair-balls never form the compact, rounded masses which are found in cattle, for the hair has little tendency to felt. The age of the patient varies greatly, the youngest, eight years old, being the case described by Dr. BUTTERWORTH, and the oldest an insane man aged 43 years. Insanity is not commonly present, only four of the 42 cases being described as mentally unsound. The quantity of hair varies; in the case described above the mass weighed when dry 3\frac{1}{2} ounces; but a hair-ball removed by PAUL SWAIN, and now in the museum of the Royal College of Surgeons of England, weighed 5 pounds 3 ounces. The hair is usually little affected, even after years' exposure to the action of the gastric juice; it is probable that the alkaline pancreatic juice would speedily erode it, or even disintegrate it, for keratin is soluble in alkalies. The general health suffers very little, but eventually pain and vomiting appear. The mass of hair is rarely vomited, and only when lit is quite small, but dyspepsia is very common. In a fair proportion of the cases the mass can be felt through the abdominal wall, and a correct diagnosis has in five cases been made; more commonly the swelling has been thought to be a malignant growth. The diagnosis is much facilitated if the patient is known to have, or to have had, the practice of eating hair, or if portions of hair are noticed in the stools. When a mass is found in the upper part of the abdomen of a child, especially if the patient is a girl, the idea of a hair-ball should enter the surgeon's mind. The only treatment is removal, and the operation has been very successful, only 1 dying out of 17 on whom an operation was performed. The prevention of hair-ball is probably not very difficult. Any child who shows a disposition to eat sand, or the wool of carpets, or to bite her hair, should be watched and care should be taken by means of nauseous substances smeared on or mixed with the abnormal article of diet to render it unpalatable to the child. The practice of eating sand is very liable to give rise to the presence of entozoa, and it should be checked at the earliest possible moment, and evidence of the presence of intestinal worms should be sought for and steps should be taken to remove them.

The Workmen's Compensation Act, 1906: A Year's Statistics.

THE Home Office has recently issued a Blue-book which deals with a new series of workmen's compensation statistics for 1908—this being the first complete year during which the extending Act of 1906 has been in operation. The volume is edited by Mr. MALCOLM DELEVINGNE, who in an introductory note explains that under the Acts of 1897 and 1900 statistics were published annually, but that these were limited in scope, referring to only seven of the chief groups of industries. The Workmen's Compensation Act of 1906 greatly extended the field of compensation. In the first place it includes, with few exceptions, all occupations, whether the employment is by way of manual labour, clerical work, or otherwise; secondly, it reduces from a fortnight to a week the period of disablement entitling to compensation; and thirdly, it extends compensation to injuries caused

by certain industrial diseases, of which a list is appended. Mr. Delevingne's work will doubtless be valuable for official purposes to certain members of the medical profession, but the statistical tables therein contained will hardly be appreciated by general medical readers without frequent appeal to the text of the statute, or preferably to a short analysis thereof, such as that which appeared in The Lancet of Jan. 12th, 1907. A translation into ordinary language of the Workmen's Compensation Act, giving a summary of its most important provisions and paged references to its several clauses and subsections, is required by medical practitioners who have no leisure to wade through the original statute.

By a statutory Order of the Secretary of State, dated Jan. 15th, 1908, returns are required concerning mines, quarries, railways, factories, harbours, docks, and shipping, these being the industries from which returns can most readily be obtained. But, with respect to the most important of the industries not included in the statutory Ordernamely, those of building, agriculture, inland transport, sea-fishing, and domestic service—no trustworthy returns are available because of insuperable difficulties in their collection. The present volume contains (1) statistics as to compensation cases in the above-mentioned Order; and (2) general statistics respecting the administration of the Act. statistical matter in the present work is presented in six tables. From Table I., which exhibits the general results, we learn that about seven and a half millions of persons in the aggregate are employed in the seven groups of industries above specified, and that in the year 1908 no less a sum than £2,080,672 was distributed among them in compensation for 3473 cases of death and 325,484 cases of disablement. These figures relate exclusively to compensation paid under the Act of 1906 to which the powers in Section 12 are limited. They do not include compensation paid under contracting-out schemes or under other Acts, or any costs or damages incurred at common law. The figures do not, therefore, represent the total charges upon the different industries in connexion with payment of compensation to persons employed in respect of injuries received. Speaking generally, we read that as regards the highly organised industries-such as mines, railways, shipping, and factories—the returns are substantially complete, whilst in other industries, more especially docks and works of construction, a margin of error must be allowed for. With reference to the administration of the new statute, we gather that only a small proportion of the claims thereunder became the subject of litigation in the courts. The returns show that among the compensations granted in the seven selected groups of industries only 1852 fatal cases and 2763 disablement cases were taken into court, a large number of which were either withdrawn or settled out of court. The number of fatal cases in which compensation was awarded by the courts was 750, or less than 22 per cent. of the total included in the returns; and the compensation awarded amounted to £123,579, or about 23 per cent. of that included in the returns. In 83 fatal cases and 311 disablement cases judgment was given for the respondent.

With reference to claims by domestic servants the

tables show that compensation was awarded by the courts in 33 fatal and 112 disablement cases, and that agree. ments for compensation were registered in respect of 61 fatal cases and 1019 cases of disablement. As regards socalled "industrial diseases," it appears that before a claim can be made respecting disablement from such disease, the workman must either have been medically certified to be suffering from and disabled by the disease, or else to have been suspended from employment under the rules of the Factory Acts on account of having contracted the disease. A table is presented summarising the returns of the certifying surgeons; it covers all the occupations to which the Act applies, and classifies the figures by the different occupations. The present volume also contains a list of 24 kinds of industrial diseases which are included under the Workmen's Compensation Act. During 1908 compensation was paid in 26 cases of death and in 2260 cases of disablement. Of these cases 1550 occurred in the mining industry; of which 386 were cases of nystagmus, 6 of ankylostomiasis, 459 of beathand, 537 of beat-knee, 67 of beat-elbow, and 87 of inflammation of the synovial membrane of the wrist-joint and tendon sheaths. Of the remaining cases lead poisoning accounts for 421, anthrax for 23, arsenic poisoning for 15, chrome poisoning for 20, and compressed-air illness for 10. No cases were returned of poisoning by carbon bisulphide, by nitrous fumes, by nickel carbonyl, or by African boxwood, nor was glanders returned as a cause of death or of disablement. Although 117 cases of lead poisoning among workers in earthenware were reported under the Factory Acts, only 100 of these were compensated during the year. A probable explanation of this discrepancy is this: that a worker suffering from lead poisoning is not necessarily entirely disabled, for in many works other employment is found for such workers, and so the mischief is stayed. Again, it is stated that although 32 cases of anthrax were reported by the factory inspectors in 1908, only 15 of these were compensated during the year. Possibly this arises from the circumstance that under the earlier Acts anthrax was held by the courts to be an injury by accident; accordingly some cases of that disease may now have been included among the accidents instead of among the diseases, as they should have been.

The section relating to medical referees appears to be one of considerable importance in view of their new relations to the question of compensation as between employers and employed. For the purposes of the Workmen's Compensation Act the number of medical referees appointed up to the end of 1908 was 344, of which 215 were for England, 83 for Scotland, and 46 for Ireland. The principal duties of a medical referee under the Act are as follows: (a) To report in cases referred to him by a judge, or by an arbitrator or committee; (b) to certify as to the condition of a workman and his fitness for employment, or as to his permanent incapacity for work; (e) to sit as medical assessor to a judge when required so to do; and (d) to decide, on appeal, against the decision of a certifying surgeon, who gives, or refuses to give, a certificate of disablement on account of industrial disease. From a series of tables relating to services rendered by medical referees we learn that 272 references were made during the year, of which 136 were made by judges, 43 by arbitrators, and 93 by committees. 35 appeals to medical referees took place against the decision of certifying surgeons, in 20 of which the decision was confirmed, and in 15 it was upset by the referee.

Annotations.

"Ne quid nimis."

THE CALENDAR OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE edition of the Calendar of the Royal College of Surgeons of England which has just been published contains some new features. A list of those who have given or bequeathed sums of money to the College is now included in the Calendar. The earliest sum mentioned is that which was paid to the Company of Barbers and Surgeons by Mr. Edward Arris in the year 1646 "for the use of the new publique anatomy." Upon the dissolution of the Barbers and Surgeons in 1745 by an Act of Parliament the Barbers were allowed to retain the whole of the corporate property, with the exception of the Arris bequest and Gale's Annuity (the latter being founded in 1655), which trusts the Act vested in the Company of Surgeons. Coming to much more modern times, it is noted that a contingent bequest of a sum of about £5000 was to become payable to the College on the death of a lady for whom the late Sir Erasmus Wilson provided an annuity. This lady has died recently and steps are being taken regarding the payment of the money to the College, but whether these steps are successful or no, the famous dermatologist will be one of the greatest benefactors of the College over which he presided, for his bequests to it, which fell in at Lady Wilson's death, amounted to some £200,000. Altogether, excluding the three sums voted by Parliament at various times, the donors and benefactors to the College number 14. Lists of the masters of the Company of Surgeons and of the members of the Court of Assistants and of the Court of Examiners from 1745 to 1800 are now included in the Calendar for the first time. The number of Fellows of the College now amounts to 1457, which number includes 1415 by examination, 28 elected as Members of 20 years' standing, 13 "by election," and 1 "elected" ad cundem. oldest Fellow is Mr. G. Carrick Steet, who was formerly chief medical officer at the General Post Office. The list of Members contains 16,957 names. The "father" of the Members of the College appears to be Surgeon-Major H. B. Hinton, late of the Bengal Medical Staff, who resides in Glenelg, South Australia, and who, in a recent letter to the secretary of the College, says: "I was born at Portsmouth on March 7th, 1813, and being at the present time in perfect health, walking for pleasure five miles or more a day. am ambitious of living to be one hundred," an ambition of which we hope to record the fulfilment.

THE BUDGET AND THE DRUG INDUSTRY.

WE referred a short time ago to the influence which the new taxes upon alcohol would exercise upon the drug industry and so upon the general practitioner who makes up his own medicines and upon hospitals and dispensaries. A notable object lesson is afforded by a price-list of one of the largest metropolitan druggists which is now before us, a list containing alterations in prices since the publication of the firm's general price-list in July. From this list we note that apparently all preparations of which alcohol forms a part, or in the preparation of which alcohol is used, have advanced

in price. Thus absolute alcohol has gone up from 4s. 4d. per pound to 5s. 5d., all the concentrated "aque" have advanced by 6d. or 9d. per pound and of course all the tinctures; the extracts also, with the exception of the watery extracts, have advanced from 3d. to 6d. per pound. It is easy to see how this advance will press hardly upon medical men and hospitals. And the medical men who will be most affected are not, be it said, men with good town practices and Cabinet Ministers for their patients, but that hard-working class of practitioners who have large contract practices and whose patients belong to the poorer section of society. This alcohol tax, too, does not touch the drinker or the publican, neither is it simply an increase of 3s. 9d. per gallon, but one of 6s. or 7s., for the alcohol used in the preparation of tinctures and the like is of 60 per cent., 70 per cent., or 90 per cent. of strength, and not ordinary proof spirit. This point was one which appealed strongly to the late Member of Parliament for Bermondsey, Mr. George J. Cooper. The manufacturer naturally recoups himself by increasing his charges to the consumer-i.e., to the medical man in a very large number of cases, but the medical man cannot as a rule increase his fees, especially in the case of club practice. Some clubs pay for their own drugs, and these clubs will feel the pinch very keenly, but it is unlikely that this fact will move the managements of other clubs to raise the salaries of their medical officers.

THE HAND AND ITS CUNNING.

PERHAPS some people would be embarrassed for a moment if they were asked to describe the ideals which led to the creation of a Philomathic Society, or at least until they had had time to reflect that the word "Mathematics" signified to the Greek in the first instance the whole field of learning. It is then only fitting that a society banded together by its common love of learning should now and then bid as the chief guest to its yearly banquet a distinguished exponent of medical knowledge. When the Liverpool Philomathic Society invited Sir Frederick Treves last week to the chair of honour it paid its homage to art no less than to science, and their guest, whose art has been shown with pen as well as scalpel, devoted his address to the praise of handicraft and in some measure to a lament for its decline amongst men. He reminded his audience that the surgeon is above all the man who uses his hands, and after asking whether mankind is, as a whole, losing that wonderful function he felt constrained to answer Yes. In spinning, weaving, sewing, carving, writing, countless human hands have been for ages employed, with the result that works of surpassing excellence and variety have been produced. None will deny that the advance of handicraft since the days when it was confined to the shaping of flints and the preparation of hides for garments has been so amazing as almost to stagger contemplation. But, says Sir Frederick Treves, with the perfection of mechanical skill the zenith of human handicraft has been passed. We are losing as a race the capacity for the finer movements of the fingers now that the loom, the sewing-machine, and the typewriter have reduced the products of a million hands into a soulless level of uniformity. Many instances present themselves to support the thesis. Metal, instead of being wrought, is cast in moulds, furniture is decorated by stamping-machines, the camera and the electric bath have well-nigh killed the engraver's art, and if there still be such craftsmen amongst us as were at once the wonder and the glory of the Middle Ages, their hands find no similar expression for their capacities, for there is only here and there a purchaser for slow-wrought and therefore costly wares. Sir Frederick Treves sighed for the day of hand-made lace and hand-made boots,

crafts of paper-making and bookbinding when carried on by hand. From his own profession he drew a striking instance of how the progress of invention may trend towards the decline of handicraft. He could imagine few phases of activity more difficult or more subtle than that displayed by the facile operator in the pre-anæsthetic days. Now there is no call to be brilliant, for the surgeon can proceed with easy deliberation, and "in place of the flashing of a blade is an action as studied as a movement on a chass board." . (We quote from the report of his speech in the Liverpool Courier.) He acknowledged that surgery has gained more than it has lost, but thought that nevertheless it no longer attains to its former perfection as a handicraft. We cannot wholly endorse Sir Frederick Treves's view here. The modern surgeon is called upon to perform manipulations in the depths of the abdomen, the pelvis, and even in the brain itself that never tried the hand and eye of the dexterous men whose exploits of amputation or lithotomy were timed by the second-hand of the watch. And in any general indictment of machinery it must be remembered that the machine may be regarded as the extension of the human hand called into existence by the exercise of the highest faculties of the brain. But we agree with much of Sir Frederick Treves's lament. The hand-made thing is almost always an honest thing, being what it professes to be, and often possessing a character and beauty that no machine can ever imitate because it depends upon a human individuality. On the other side, art will never perish from the world, even though it be less and less applied in common craftsmanship. When, for instance, China has "occidentalised" herself her artists will doubtless desist from the carving of concentric hollow spheres in patterns of bewildering intricacy and will turn to more fruitful occupations, but we cannot think that the cunning spirit made manifest in the ivory will fail to find new expression amongst the people who gave it birth. Rather we believe that men of the crafts which have produced lovely things for many centuries will find the artistic energy that directed their fingers passing into new forms of usefulness and beauty.

ORGANO-THERAPY IN ADDISON'S DISEASE.

It is a curious fact, for which no explanation has been given, that while organo-therapy has been perfectly successful in myxcedema, in no other disease supposed to be due to failure of an internal secretion has it given a similar result. The evidence of its value is unsatisfactory. This fact is well illustrated by the adrenal in treatment of Addison's disease, which has proved disappointing. However, a few cases have been recorded in which the disease seems to have been cured. At a meeting of the Académie de Médecine of Paris on Oct. 5th M. E. Boinet read an important paper on the organotherapy of Addison's disease and reported 8 cases in which he had adopted it, with the following results: 1 case of cure, 3 cases of considerable improvement, and 4 cases of failure. In the first case a pedlar, aged 34 years, was seen in April, 1898, with all the classical symptoms of Addison's disease. There were characteristic marked melanodermia and brown spots on the internal surface of the lips and cheeks, on the gums, on the palate, and on the tongue. The patient was very feeble and was fatigued even when at rest. He was very wasted, weighing only 60 kilogrammes. Organotherapy was at once begun and consisted in the daily ingestion of two fresh suprarenal capsules of the sheep and in the subcutaneous injection of a glycerine extract of the suprarenal capsules of the calf, at first every fourth day, then every second day. In order to obtain a more rapid result the patient tripled and even quadrupled the does and every book-lover will join with him in his eulogy of the This was followed by tremors, a result which M. Boines

has shown to be due to overdose of adrenalin. the end of six weeks nervous troubles appeared, and there was continuous tremor, increased by movement and most marked in the upper limbs, particularly in the hands. In November, 1899, 120 injections had been given and there was considerable diminution of all the symptoms. The improvement continued, and now, at the end of 10 years, the melanodermia is scarcely perceptible and the spots in the mouth have almost disappeared. The patient weighs 100 kilogrammes and can walk all day without fatigue. Béclère has recorded a very similar case. The patient was a man, aged 24 years, who had suffered for 15 months from typical Addison's disease, which was progressing rapidly. ingested daily four suprarenal capsules of the sheep weighing from 10 to 15 grammes. A month later 1 cubic centimetre of the glycerine extract of the suprarenal capsules of the calf was injected daily. After four and a half months' treatment he had gained 10 kilogrammes in weight and had almost completely recovered. Now, 11 years later, he is in good health. M. Boinet suggests that in such cases the adrenalin causes hypertrophy of portions of the suprarenal capsules which have remained sound. It sounds to us more probable that by supplying the deficient internal secretion it improves the health of the patient and allows the vis medicatrix natura to produce the hypertrophy. In one of the cases of improvement reported by M. Boinet the patient was a woman, aged 66 years, with the characteristic pigmentation of the skin and mouth. She was very weak and was fatigued by the slightest effort, and suffered from lumbar pain and gastro-intestinal troubles. She took by the mouth daily extract of the suprarenal capsules of the calf. After some months she had almost completely recovered from the weakness, but the pigmentation was unchanged, and she also had tremor of the fingers. She still remains in this state nine years after the commencement of the treatment. In the other cases of improvement the result was similar. In the cases of failure some temporary improvement was obtained, but symptoms of acute suprarenal insufficiency eventually supervened and rapidly proved fatal. M. Boinet has described under the name of "Addisonism" a group of symptoms consisting of pigmentation and debility falling short of those of Addison's They are not undisease due to suprarenal inadequacy. common in pulmonary tuberculosis, thus differing from true Addison's disease, which is a primary tuberculosis of the suprarenal capsules. In this condition the suprarenal capsules are sclerosed, but not completely destroyed. Suprarenal treatment is very successful. M. Boinet therefore suggests that the cases of recovery from the symptoms of Addison's disease under adrenalin may be cases of "Addisonism" and not of true Addison's disease.

THE PATHOLOGICAL ANATOMY OF MONGOLIAN IDIOCY.

THE pathology of this common form of imbecility is still not clearly determined. While some consider it due to an agenesis of the nervous centres, others think the maldevelopment is secondary to the ordinary processes of meningitis or chronic meningo-encephalitis. In the Archives de Médecine des Enfants for July will be found a carefully described examination of the central nervous system of a case of the disease by Dr. Babonneix, working in the laboratory of Professor Raymond in Paris. The child, who presented the usual anatomical stigmata, and in addition had symmetrical syndactyly of the middle toes and double cryptorchidia, died at the age of five years from tuberculosis. The convolutions of the brain were simple and the fissures shallow, but no obvious anomaly was otherwise visible. The pia was thickened and somewhat adherent, but it could be stripped without decortication. Scattered irregularly over the surface of the brain

were small areas of meningitis, with unmistakeable vascular alterations in the shape of dilatation of vessels, interstitial hæmorrhagic foci, and peri- or paravascular inflammatory nodules. Microscopical investigation of the cortex showed that in some places it was sclerosed and demyelinised, while the cellular elements were often rarefied, sometimes disarranged, staining badly, and exhibiting granulation of the protoplasm. Many nerve cells were seen embedded in the white matter. The systems of tangential fibres had almost entirely disappeared. cortical neuroglia was intensified and unusually rich in spider cells. Throughout the brain the blood-vessels were congested, with dilatation of the perivascular sheaths; deposits of pigment were seen frequently in their neighbourhood. In the lower nervous centres only minimal changes were observed. The pyramidal tracts were agenetic. From a correlation of the work of others Dr. Babonneix considers the view incontestable that the agenesis of the nervous centres is secondary to a process of chronic meningitis. The nature of this meningitis remains sub judice.

THE OPENING OF THE ROYAL EDWARD INSTITUTE AT MONTREAL.

On Oct. 21st the Royal Edward Institute, which has been erected at Montreal for the study and treatment of tuberculous disease, was opened by the King, who was at the time four and a half thousand miles away. The ceremony consisted in the hoisting of the Royal Standard, the opening of the main doors of the institute, and the switching on of its lights, the necessary machinery being set in motion by a weak electric current transmitted across the Atlantic from Chichester, where His Majesty completed the circuit at West Dean Park. He pressed the necessary button at 9 o'clock P.M. Greenwich time, and within a second the ceremony had been performed at Montreal, the time there being 4 P.M. Sir Charles Fitzpatrick, Deputy Governor of Canada, attended the ceremony in the unavoidable absence of Lord Grey, and addressed a large and brilliant assembly who also heard speeches from Sir George Drummond, chairman of the institute, and Dr. R. W. Philip of Edinburgh, its designer. The King telegraphed the following message to the chairman immediately after the opening had taken place :-

"I have much pleasure in declaring the Royal Edward Institute, Montreal, now open. The means by which I make this declaration testifies to the power of modern science, and I am confident that the future history of the institute will afford an equally strong testimony to the beneficent results of that power when applied to the conquest of disease and the relief of human suffering. I shall always take a lively interest in the institute, and I pray that the blessing of the Almighty may rest upon all those who work in and for it, and also upon those for whom it works.

EDWARD R. AND I."

THE DIAGNOSIS OF TUBERCULOUS MEDIASTINAL GLANDS.

WE published in our columns last week a note by Dr. John Allan on the importance of the early recognition of tuberculous mediastinal glands. The possibility of latent pulmonary tuberculosis in children is now generally recognised. The etiology has been further explained by researches which prove that the pathogenic bacilli may pass through the walls of the healthy intestine and become lodged in the mediastinal glands, so that infection through milk from a tuberculous cow may thus take place. Dr. Allan points out that in the study of latent pulmonary tuberculosis we are confronted with a difficult problem, and many points have to be carefully considered in the endeavours to deal correctly with it. He deals mainly with

the diagnosis. The symptoms are numerous and often vague; loss of weight, ansemia, afternoon fever, and cough are the commonest, likely to mislead if occurring singly, but of much significance when combined. The physical signs in some instances may be obvious, but in the majority of cases are ill-defined. By a careful study of these points a presumptive diagnosis may often be arrived at. Dr. Allan then draws attention to the auxiliary methods of diagnosis. which may be of the greatest aid, but unfortunately require, for the most part, the assistance of a colleague in the laboratory or an X ray installation. The value of the Roentgen rays in diagnosis has been much disputed. Dr. C. W. Cunnington has pointed out that in the "right oblique" position an excellent view may be obtained of the posterior mediastinum, which appears as a triangular light space, which in health is clear and becomes markedly luminous on deep inspiration. He finds that when the retrocardiac glands are enlarged the space remains dark and is of opinion that children presenting this condition should be considered tuberculous. French authorities have long recognised the possibility of such early diagnosis, and institutions for tuberculous, or "tuberculous-prone," children are more numerous in France than sanatoriums for adults.

THE LATE OUTBREAK OF CHOLERA IN THE PRESIDENCY GENERAL HOSPITAL, CALCUTTA.

THE Lieutenant-Governor of Bengal, as we announced last week in a leading article, has issued an official report describing the outbreak of cholera which occurred in the Presidency General Hospital, Calcutta, in July last, and embodying the results of bacteriological examinations carried out by Professor Haffkine. The first case, that of one of the nursing staff, occurred on the morning of July 30th. and was followed by ten other cases during the day and on the subsequent day. Six deaths resulted among the nursing staff, the other fatal cases being those of three children, who were in-patients of the hospital, and a native sweeper. All the cases occurred within 30 hours of the first, and so virulent was the infection that, although treatment was adopted immediately, death followed in the fatal cases within 24 hours from the first symptoms. No case occurred after midday on July 31st and the epidemic stopped as suddenly as it began. Careful investigations showed that those affected all partook of the evening dinner on July 28th and that the infection was carried in some article of food supplied at this meal, prob. ably a custard served with stewed fruit, of which they had all eaten. On July 31st Professor Haffkine isolated comma bacilli in pure culture from the stools of five of the patients, thus eliminating the possibility of ptomaine poisoning, which was at first suspected. He also took 127 samples of food and water, and on bacteriological examination 14 were found infected with comma bacilli. The uniformity of infection led him to suspect the kitchen servants as possible sources of the infection, and of 12 servants examined two masalchies (natives who wash up dishes, plates, &c.) employed in the nurses' kitchen yielded positive results, comma bacilli being actually found on their hands. One of these just before examination had visited the latrine and washed at the place set apart for servants. This circumstance suggests that the men, or some of them, were actually harbouring comma bacilli and acting as "carriers," as has been proved to be the case in enteric fever. Contaminations could be conveyed from their hands to the dishes and in this way to the dining room. Professor Haffkine segregated these men and examined their excreta. finding comma bacilli, of which he is still engaged in working out the cultural properties. If the custard was inoculated in the morning with comma bacilli and allowed to stand at the temperature of a July day in Calcutta it

would present a teeming mass of virulent bacilli before evening time, when it was partaken of by those who contracted the disease; and the incident serves as a most tragic illustration of the dangers run by tropical residents whose servants exhibit any uncleanliness in the preparation of their food. It also seems to prove beyond dispute the dangerous existence of cholers "carriers."

ISOLATED FRACTURE OF THE TRANSVERSE PROCESS OF A LUMBAR VERTEBRA.

OF the exact pathology of the condition termed sprain of the back little is known, and its diagnosis from lumbago, which, as is well known, may be of very sudden onset, is sometimes difficult. The X rays have recently thrown some light on this injury and, as in other regions, have revealed the existence of fractures previously unsuspected. In March, 1908, Ehrlich described what he thought was the first case of isolated fracture of the transverse process of a lumbar vertebra which had been diagnosed during life.1 Three cases in which this injury was found post mortem had previously been recorded. In December Haglund added seven other cases.2 In all these cases the diagnosis was made by means of the X rays. In the New York Medical Journal of Oct. 9th Dr. S. Lange, radiographer to the Cincinnati Hospital, has reported two other cases. In the first the patient was a muscular man, aged 50 years, who said that four months previously, while lifting a heavy tray out of a trunk, he felt something give way in the small of the back. pain followed and he had to cease work. Next morning, while bending over the washstand, he felt excruciating pain in the same place and fell to the floor, from which he could not rise for a few minutes. Since that time he had been unable to follow his occupation of commercial traveller because of the pain, which was especially marked on stooping, riding on cars, and walking fast. At night, when in bed, he occasionally felt twinges of pain. On examination all that could be found was an area of acute tenderness of about the size of a dollar to the left of the last lumbar vertebra in the angle between the crest of the ilium and the spine. To this spot the patient referred all his pain. It resisted all the usual methods of treatment, including rest in bed, strapping, salicylates, and potassium iodide. rays revealed a fracture of the left transverse process of the fifth lumbar vertebra. The process was tilted up at an angle and an irregular fissure separated its tip from its base. Some union of the fragments seemed to have occurred. It appeared that the patient's powerful erector spinæ in contracting broke the transverse process. In the second case a man, aged 35 years, was admitted to hospital complaining of severe pain in the right lumbar region, which began two days previously after a sharp blow in the small of the back from a heavy, rapidly revolving crank-handle. Examination showed rigidity of the lumbar muscles on the right side and great tenderness on pressure to the right of the first lumbar vertebra. Skiagraphy revealed a fracture of the right transverse process of the first lumbar vertebra, with upward displacement of the fragment. The causes of the fracture in the cases reported by Haglund are instructive. In one case a coal bucket fell upon the lumbar spine: in two the back was "sprained" while riding a bicycle; in a third instance a man sprained his back whilst lifting his son; another fell downstairs; and the last patient was an athlete who had many times fallen on his back but could not say which fall had caused the fracture. Before the application of radiography to this class of injuries these fractures must have been diagnosed as sprains. The diagnosis

Deutsche Zeitschrift für Chirurgie, Band xeil., p. 413.
 Ibid., Band cxvi., p. 321.

may be based upon the history of the accident, tenderness on pressure over the seat of fracture, slight muscular rigidity, and pain of varying severity, which is increased by movements of the trunk, especially walking and stooping, and relieved by lying down. If the case is seen late the diagnosis can be made only by radiography. The diagnosis is of medico-legal importance, for in many obscure cases claims for compensation are made for injuries to the back. In the past objective signs could not be found in cases of this fracture, but now radiography may prove useful.

THE REMUNERATION OF MEDICAL MEN SUMMONED ON THE ADVICE OF MIDWIVES.

IT will be remembered that the recommendations of the Departmental Committee appointed by the Lord President of the Privy Council to consider the working of the Midwives Act, 1902, are as follows:-

Act, 1902, are as follows:—

A secure expectation of payment should be given to a medical practitioner summoned on the advice of a midwife in a case of amergency. The Poor-law authority should be responsible for the payment and should be empowered to charge the fee paid as "relief on can" to the patient. The scale of fees should be fixed by order of the Local Covernment Board on a systematic basis, having due regard to local conditions. In emergency cases the system of a uniform fee, which should cover any ordinary after-attendance, is recommended for adoption, with the addition, perhaps, in scattered rural areas, of some allowance for mileage. The medical practitioner, in applying to the public authority, should be required to state that he has been unable to obtain payment of his fee from the patient or her representatives. A list of practitioners willing to respond to a midwife's call should be prepared and circulated in every area.

The Council of the London and Counties Medical Protection Society has just approved the following recommendation of its Midwives Committee :-

That having regard to the proposed payment by boards of guardians of the doctors called in to assist midwives, the London and Counties Medical Protection Society recommends the medical men in each union to meet and confer on the subject, and to agree as to what fee or fees they will accept, and then combine to insist on such fee or fees being paid (or guaranteed) by the guardians, and paid on the statement of the medical man that he is unable to obtain payment of his fee from the patient or her representatives.

DISEASE OF THE PITUITARY AREA AND CHANGES IN BODILY NUTRITION AND DEVELOPMENT.

RECENT studies, based on a consideration of clinical and pathological material, of the question of the relation of disease of the pituitary gland and its appendages to disturbances of bodily nutrition, arrest of bodily development, defective appearance or absence of secondary sexual characteristics, and so on, have served to show that the subject is a highly complex one, and its complexity seems to increase with advancing knowledge. The inter-relation of the various ductless glands and their cooperative function in the bodily economy are matters which are far from being fully elucidated. The well recognised and familiar condition known as acromegaly, in which the extremities in particular are overgrown, is frequently associated with tumours of the hypophysis, but not necessarily so. Some cases of that disease are sexually infantile, and in them secondary sexual characteristics are undeveloped. Loss of sexual appetite is apparently a symptom of early establishment in pituitary disease, though it is common in many intracranial growths. Further, there is a well-differentiated type of somatic and sometimes mental infantilism in which the body becomes fat, pubic and axillary hair does not grow, the testicles remain atrophic (degeneratio adiposo-sexualis), and this type is associated with pituitary disease—it is supposed defective function of the anterior lobe. In some cases of gigantism—a condition distinct from acromegaly disease in the region of the sella turcica has been found. In the skeleton of the Irish giant Magrath, described by the late Professor Cunningham, the cranio-pharyngeal canal is patent. Some giants are also sexually infantile. secondary sexual characteristics of the female, have sometimes been associated with bitemporal hemianopia and primary optic atrophy-indications of disease in the pituitary neighbourhood. It is evident we have not as yet reached the stage at which a pathological diagnosis can be made with certainty. In the Wiener Klinische Wochenschrift of April 29th Dr. Formanek describes the case of a girl, aged 18 years, who from early childhood had been backward physically and mentally; her bones were thin and small, the mammæ were undeveloped, and she had never menstruated. When she came under observation she complained of headache and inordinate sleepiness. Apparently no definite sign of intracranial disease was discovered. There is no mention, however, of the visual fields. Under observation she became steadily weaker, mentally and physically, and began to lose weight in a remarkable way. Just before her death, some months later, her weight was only 42 pounds. At the necropsy a cystic tumour was found growing from the base of the skull, impinging on the third ventricle, and bounded anteriorly by the chiasma, posteriorly by the cerebral peduncles, and laterally by the temporal lobes. The clinoid processes of the sella turcica were flattened, but the pituitary body itself was of normal size and in its normal position. The tumour was a squamous-celled epithelioma and grew from the epithelium lining what had been the duct from the pharynx to the hypophysis. In other words, it was of ectodermic origin, springing from the "rest" of that part of the stomatodæum of the embryo which passes upwards and backwards to the base of the skull. The ovaries and the genitalia were infantile. The interest of the case is obvious, but it leaves many problems as far from solution as before.

THE NORFOLK AND NORWICH HOSPITAL.

EXCELLENT work has been done by the physicians and surgeons of the ancient city that will always be honoured as the birthplace of Sir Thomas Browne, and the present practitioners in Norwich live up to their great traditions. Here for 140 years Norfolk has had its county hospital, the existence of which has been of the utmost benefit to medicine no less than to the sick poor of a wide area, and this institution has enjoyed the special patronage of the King and Queen since Their Majesties, when Prince and Princess of Wales, became residents in the easternmost county. His Majesty laid the foundation-stone of the present buildings 30 years ago, and visited the buildings in 1884, the year after they were opened by the Duke and Duchess of Connaught. Since that time the work of the hospital has greatly increased, there being at present over 200 beds available for occupation. In 1907 the honorary medical staff prepared at the request of the board of management a report setting forth the additions and improvements which they considered necessary for the maintenance of the hospital at a proper level of efficiency for modern treatment, and just a year ago this scheme was presented to the general board of management, showing that the improvements chiefly needed were as follows: the provision of new isolation and septic blocks, the present accommodation for infective cases being in the oldest part of the building and quite inadequate; new operating theatres; alterations in the out-patient and casualty departments; and additional quarters for the nurses and ward-maids. With some smaller requirements the estimated cost of these improvements was nearly £44,000, and the governing body, which is only able to meet current expenses with the help of legacies, recommended that no part of the work should be undertaken unless an endowment was forthcoming at least equal to the cost of building that part: A Cases of "feminism," where the male takes on the vigorous appeal during the past year has resulted in

sufficient funds being raised to satisfy this condition so far as concerns the isolation and septic blocks, which together will cost some £5600. The interest of the King was aroused in the scheme, and on Oct. 25th His Majesty visited Norwich, where he was received in state by the city fathers in their old St. Andrew's Hall, and was acclaimed with the utmost heartiness during his drive through the city. After reviewing and presenting colours to the Norfolk Regiments and the Royal Norfolk Yeomanry, he proceeded to the Norfolk and Norwich Hospital, where he was received by the Earl of Leicester, its president, who at the close of a religious service presented with a loyal address of welcome. In replying, the King paid a warm tribute to the memory of the late Lord Leicester, and expressed his gratification at being able to inaugurate the necessary extension of the hospital, the needs of which he commended to the support of the charitable. He concluded with these words: "The encouragement you give to your nurses to join the Nursing Service of the Territorial Forces meets with my most cordial approval. In matters of life and death the services of the trained nurse are no less essential than those of the physician or surgeon. I pray that the blessing of God may rest upon your labours." foundation-stone was then "well and truly laid" by His Majesty, who took his leave after a benediction had been pronounced by the Bishop of Thetford. We trust that the work begun under such fortunate auspices may not be hampered for lack of further funds, the more especially as there has been a suggestion of forming an adequate ophthalmic department by amalgamation with the Norfolk Eye Infirmary, which, if carried out, may necessitate an expenditure considerably beyond the present estimates.

THE DANGER OF FAST DRIVING.

THE sentence of eight months' hard labour recently passed upon Arthur Saytch at Devizes by Mr. Justice Phillimore cannot be regarded as undeserved. It is not necessary to describe the manner in which he drove into the rear ranks of a battery of Territorial artillery on the march in the early morning on Salisbury Plain, killing one and injuring others, as the inquest, the hearing before the magistrates, and the trial have been fully reported. It is satisfactory that conviction should have followed upon the proceedings taken by the Treasury, for a coroner's jury had failed to find a verdict of manslaughter, and acquittal might have given rise to the feeling that the action rightly taken on behalf of the Crown was oppressive and vindictive. Other drivers of motor-cars will do well to consider the futile nature of the excuses raised in his own defence by the prisoner, of which the most plausible no doubt was that he drove suddenly into thick mist which prevented him from seeing the soldiers in front of him in time to pull up. All motorists are aware of the almost amazing rapidity with which a motor-car in good order can be stopped in favourable circumstances, and those who do not drive motorcars will not contradict them. What motorists, however, apparently fail to realise is that the human as well as the mechanical element in the operations necessary to stop a motor-car have to combine in the consecutive performance of their functions in a space of time which leaves no margin for the correction of errors. The motor-car which is being driven without infringing the letter of the law as to speed at the rate of 20 miles an hour traverses, roughly speaking, 10 yards in a second, and consequently the driver who first comes in sight of an obstacle when it is at a distance of 10 yards approaches 2 yards nearer to it in every fifth part of a second occupied in appreciating the situation, in making up his mind what is to be done.

and in performing the physical acts necessary before any diminution of speed commences. Similar considerations apply to foot passengers, and at the recent inquest upon an elderly retired naval officer, who was run over at the bottom of Regent-street, it was made apparent that there was no excessive or dangerous speed on the part of the vehicle which caused his death, but that the accident was due to momentary hesitation on his part. There was time for him to have passed into safety, but there was none in which to correct an error once made. Subways are sometimes suggested as a preventive of street accidents of this kind, but it is doubtful whether they would be of great practical utility, even though they were to be adepted on a large scale. The young and active would not welcome the delay and extra trouble entailed by using them, and the descent and ascent of flights of stairs are irksome to the elderly and infirm; whereas young and old alike have a perfect right to use the highway and to have their safety considered by those driving along it. The punishment of those whose want of such consideration is proved against them should act as a warning to reckless and callous persons. A considerable, and indeed extraordinary, increase of street accidents within the metropolitan area due to vehicles of all kinds is recorded, and it will be interesting to observe whether they diminish or not during future years, as drivers and pedestrians alike become accustomed to the new conditions under which an augmented and accelerated vehicular traffic is conducted.

THE FRANCO-BRITISH EXHIBITION AND KING EDWARD'S HOSPITAL FUND FOR LONDON.

THE honorary secretaries of King Edward's Hospital Fund for London have received a cheque for £4775 from Sir Charles Hardinge, together with a letter, in the course of which he states: "According to Clause VIII. of the Articles of Association of the Franco-British Exhibition, Incorporated, any surplus remaining after the liquidation of that association is to be devoted to some public object or objects, charitable or otherwise, to be determined by the Secretary of State for Foreign Affairs for the time being, and the Minister whom the association shall select as holding similar office in the French Government for the time being. A cheque for £4775 has been forwarded to the French Ambassador, and I am now directed by Secretary Sir E. Grey to transmit to you herewith a cheque for a similar sum, representing the other moiety of the present available surplus, which the Secretary of State desires to place at the disposal of King Edward's Hospital Fund for distribution to British hospitals in London."

OCCUPATION NEUROSES.

THE statement that nervous disease is on the increase has become somewhat of a commonplace, although a distinction is not always properly drawn between the actual multiplication of cases of a disease and its better recognition. The number of patients who attend out-patient departments complaining vaguely of "their nerves" is noteworthy. malaise of indeterminate origin is attributed to the nerves, and the task of dissecting the imaginary from the real frequently calls for the most exemplary patience on the part of the examiner. There is a vast field of minor nervous disorders, of which the remark of Pitres is profoundly true, that "les maladies les plus faciles à observer ne sont pas toujours les mieux connues." Among these the so-called professional cramps occupy a foremost place. A professional cramp is an affection characterised by tonic or clonic convulsive movements, or by trembling or tremors, or paresis or palsy, which occur solely during the execution of a particular professional act, and are localised in some or all of the muscles which cooperate synergically in the performance of

that act. Professional dyskinesis, or occupation neurosis, is a preferable term. For the production of the condition the combination of a congenital predisposition with frequent repetition of the same functional act is essential; neither by itself is capable of establishing an occupation neurosis. It is more than 40 years since Duchenne of Boulogne ascribed the trouble to some central disturbance, and more than 30 since the late Dr. Vivian Poore advocated the peripheral theory in the pages of THE LANCET. Whichever be the view adopted, the importance of the mental factor must not be lost sight of. Mild local affections, such as arteritis, synovitis, myositis, and neuritis, have been noted, but they are inadequate to explain the specialisation of the neuroses. If we say that certain nerve cells concerned in the coördination of professional acts, and excited or exhausted by overwork in a predisposed individual, undergo a dynamic alteration whereby they respond to further calls on them by spasms, tremors, or paralyses, we have expressed all that is at present likely to be learnt of the pathogeny of the occupation neuroses. Yet they are being added to almost daily; automobilists' cramp appears to be the latest arrival. In a series of articles which have been furnished to the Nouvelle Iconographie de la Salpêtrière, M. Macé de Lépinay has given an admirable study of them. consideration of the all-important question of prognosis M. de Lépinay says must be based on four factors: the exciting cause, the presence or subsequent development of other neuroses, the patient's mental condition, and the duration of the affection. Prophylactic treatment is, of course, often impossible. Treatment by drugs is mostly immaterial. Physical treatment consists in professional rest, which is neither sufficient nor indispensable in M. de Lépinav's opinion, in local or general applications of electricity, massage, local and general hydrotherapy, and in particular in the "hydromineral cure," a method much vaunted in France at present. Psychical treatment is the necessary complement of the physical, and consists in patient, methodical, progressive muscular re-education or kinesitherapy. Combine with this the efficacious action of psychotherapy, and the physician has a weapon at his disposal in the guise of psycho. motor discipline with which occupation neuroses can often be most successfully combated.

PLAGUE shows no abatement in Mauritius. The Governor has notified the Secretary of State for the Colonies that 25 cases with 11 deaths were reported during the week ending Oct. 21st.

Dr. Norman Moore, physician to St. Bartholomew's Hospital, has been elected to an honorary Fellowship of St. Catherine's College, Cambridge.

MEDICAL SICENESS AND ACCIDENT SOCIETY.—
The usual monthly meeting of the executive committee of this society was held on Oct. 15th, Dr. de Havilland Hall being in the chair. The accounts presented showed a great falling off in the sickness claims, both in number and duration, during the summer months as compared with the experience of the winter. In a society formed for the most part of medical men in general practice, and therefore liable to exposure to bad weather, it is clear that such a result as this must be looked for. The financial results of the year's working have so far been very satisfactory, and, as in every previous year of the society's history, a substantial addition has been made to the invested reserves. Prospectuses and all further information may be obtained on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33, Chancery-lane, London, W.C.

SOME CONSIDERATIONS OF MEDICAL EDUCATION.

II.1

The One-portal System.—The Introductory Examination in General Subjects.—The Examination in Preliminary Scientific Subjects.

THE state of the medical education of the country is dependent equally upon two things: the opportunities for the acquisition of learning and practice offered at the centres of medical instruction, and the methods of testing the knowledge of the students which are employed by the various degree- and diploma-granting bodies. To report upon these opportunities and methods in complete detail would be entirely without the scope of these articles, for such a programme would imply the description of the state of every dissecting-room, of the standard demanded by every examiner in every subject, of the ability displayed by every lecturer on medical matters, and so on. Some such complete dealing with the subject was possible 30 or 40 years ago, both the number of medical centres and the number of subjects included in the medical curriculum being so much smaller. Now it is no longer possible, but fortunately there is no need whatever for it, as there are many easily accessible sources for much of this varied information, while there is good evidence to show that the medical education of the student at all the different centres presents many similar features, and the controlling power of the General Medical Council makes it certain, as we have seen, that the examinations which close these similar curriculums will themselves be similar. This fact has seemed to many to be in itself a fairly complete answer to those who advocate the institution of a one-portal system, under which all men would enter the medical profession after passing one State examination. The essential features of such a system, they say, are already present in our scheme of medical education, for, whatever the educational body under whose ægis the student decides to enter the medical profession, his examinations will be arranged upon a common plan and brought up to acommon standard by the central authority. But the answer does not meet the case in all directions. When medical education was a much simpler affair and when almost every medical man in England (for example). became qualified as a Member of the Royal College of Surgeons of England or as a Licentiate of the Society of Apothecaries of London, or as both, as far as England was concerned, something like a one-portal system did exist, the presence on the Register of the names of an inconsiderable number of graduates of three or four universities not giving rise to any grave feeling of class distinction between the membersof our learned profession. Certainly the English diplomates sometimes displayed a little acerbity with regard to the privileges allowed to Scottish graduates in medicine whose training was in no way superior to their own, a feeling whichwas faintly shared by Irishmen; but, roughly speaking, the vast majority of medical men entered the medical profession in the same way, and the only graduation in rank recognised among themselves was due to the class of their work. Now this is all altered. The methods of entrance to practice are not only numerous but dissimilar to an extent which the supervising authority of the General Medical Council cannot alter, though maintaining a good general standard; and the departure from a one-portal system has become very complete.

The part of supervision played by the General Medical Council is to admit the student to the roll of the profession when he is successful in obtaining the necessary qualifications, and to see that those qualifications are adequate. The

¹ No. I. was published in THE LANGET of Oct 23rd, p. 1232.

part played by the qualifying body is to examine him at different stages of his career, guaranteeing that he does not enter for those examinations until after the attendance at certain classes, and the expiry of certain time. The first step in the education of the medical student is his registration, and the registration of a student is not compulsory. The General Medical Council has laid down regulations in reference to the registration of students which are very precise, but there is nothing in the Medical Acts making it incumbent upon the student to enter his name with the Council at the commencement of his studies. It is sufficient for his name to be enrolled by his qualifying body upon passing one of the statutory preliminary examinations; that body becomes responsible for not admitting him to his final examination until five years later. It is important to remember exactly how the matter stands, as upon this very point of registration some quite acute differences of opinion

The preliminary examination, as provided for by the General Medical Council, supposing the student not to begin his studies by passing any recognised test at his university or corporation, is of fair scope, though it might be made harder, and the degree- and diploma-granting bodies have shown their readiness to comply with the modest requirements by instituting tests at least as rigorous as the statutory recommendations enjoin. The matriculation of the University of London is harder than the examination which opens up the career of medicine at other centres, but of recent years that examination has been modified, and exemption from it has been granted to medical students who have passed easier tests. But far more application is required from the student to pass the matriculation examination at the University of London than is required to pass any of the other entrance examinations, and the student who has passed it should be able to assimilate with greater ease the subjects of the purely professional examinations, but this depends a little upon the way in which he has learned his work. A number of those who matriculate at the University of London have been most laboriously coached; they can reproduce answers to many questions, but it seems to be a general opinion that in too many instances they acquire habits of working which do not tend to make of them practical medical men. The General Medical Council might well insist upon an all-round raising of the standard of general education, but in so doing it is necessary that any premium on cram should be avoided. Elasticity in the educational curriculum is more and more wanted as we grow to perceive that there is room in the ranks of the medical profession for workers of every kind.

The next step in the education of the medical student brings us to a point around which discussion rages. It is difficult enough to decide what subjects are strictly professional and what subjects are preliminary to the study of medicine, but it is doubly hard to arrive at a definite opinion how far it is well that the student should have acquired any knowledge of the preliminary subjects before beginning his curriculum of five years' study as a medical student proper, registered or unregistered. For the proper teaching of anatomy and physiology a medical school is required, but for instruction in zoology, chemistry, and botany, supposing botany still to be required as a compulsory subject apart from morphology, no medical institution is necessarily demanded for the student's work. Theoretically, as we said in the previous article, the preliminary scientific examination, the subjects of which are chemistry, botany, biology, and physics, should be passed at the end of the first year of the curriculum, leaving the student free to devote two full years to the study of anatomy and physiology and two full years to work in the wards, with the chance of obtaining his qualifications as a

qualified medical man within five years. The questions which immediately arise are: Can a knowledge of chemistry, botany, biology or zoology, and physics be acquired in a year with sufficient fulness to be of permanent value to the student? Is there not a risk either that mere smatterings only will be. learnt or that the student in his desire to enter more fully into the subject should fail to be ready for his examination at the end of a year; in other words, should encroach upon time which ought to be, or is designed by the General Medical Council to be, devoted to purely professional subjects? Some observers, those who are best satisfied with the position of things as they are, and are the most certain that progress in medical education is taking place along the right lines, will say that a year is quite sufficient time in which to obtain familiarity with the principles of chemistry, botany, biology, and physics if the instruction in those subjects is given only with direct reference to medicine, it being, of course, understood that the examiners in testing the knowledge of the students will be careful to observe the same limitation. authorities conceive that to ask the student to spend only a year on these subjects is to invite him to obtain a verbal acquaintance with things which he does not understand, and must tend to divorce the practice of medicine from its proper adherence to the sciences with which it should be indissolubly blended. The importance of the difference of views thus expressed is accentuated by the fact that each party would logically desire a different course of proceeding in the mechanism of medical education, and though the truth may lie between the two extreme points of view it is not easy to advise an intermediate course of action which should correspond with that intermediate truth. Those who desire that the medical student should be educated in the preliminary scientific studies solely with the eye to his use of those studies in the practice of medicine will naturally hold that he should study those subjects in a medical school. Those who consider that the medical student, especially, for example, in such subjects as biology and chemistry, should receive thorough and systematic teaching on general lines-any medical application of what he has learned being allowed to reach him afterwards—would wish that the systematic teaching should be given at a scientific institution or as part of a general university curriculum, and not at a medical school. Now, although it is possible to devise a schedule for the examination of medical students in the preliminary scientific subjects which shall on the one hand be fairly general and systematic, and shall on the other have obvious applications to medicine, it is not easy to devise an institution for the teaching of these subjects which is both a medical school and not a medical school. For this reason those who desire that the lad should learn his preliminary scientific studies at school before beginning his professional course and those who wish him to learn them at medical schools cannot agree, for the strong points in the arguments of each are not open to compromise.

And the whole situation is further complicated by the fact, to which allusion has been made already, that the registration of the medical student not being compulsory the General Medical Council, the central authority of medical education, has no hard-and-fast jurisdiction over the beginning of the course. If registration as a student were compulsory upon the medical student it would be easier for the General Medical Council to ensure that instruction in these preliminary subjects was only acquired at certain places where the standards and facilities for learning appeared to the Council as the central authority to be satisfactory, but registration not being compulsory the duty of the Council is confined to registering the student as

a practitioner when he has passed all the necessary tests, it being left to the particular educational body by which he is entering the profession to ascertain, by any system which seems good, whether he has spent the necessary time upon his curriculum and to guarantee to the Council his due observation of the statutes. It follows from this that a student can learn his preliminary scientific subjects either at a medical school, or at a public school, or at a university, exactly as he likes, if the body under whose ægis be intends to enter the medical profession is satisfied with the place where he has obtained his instruction. The position thus arrived at may appeal by its flexibility to those who find that our educational courses have in every walk of life a great tendency to become too confined by regulations and too cramped by syllabuses, but it is not a universally fair one. Thus one student may enter, say, in October, 1909, at the medical school attached to one of the metropolitan hospitals with the expectancy of becoming a qualified medical man at the end of 1914. He then proceeds to learn at the medical school his preliminary scientific subjects. Another student of the same age may learn his preliminary science subjects at a public school where the course is approved by the Conjoint Board of the Royal College of Physicians of London and the Royal College of Surgeons of England. He need not enter a medical school at all till 1910, and will do so having passed not only his entrance examination but his examination in preliminary science subjects. He will have enjoyed the advantage of one more year in the sheltered life of a public school and will possibly have learned his preliminary scientific subjects better from a general point of view than he would have learned them at many of the London medical schools, which schools labour manfully under great disadvantages in instructing their pupils. Until quite recently the student under the English Conjoint Board who entered the medical school in 1910, having done his preliminary scientific course at school, was able, like the student who entered in 1909, to sit for his final examinations in 1914, the last year of his school life counting as the first year of his medical curriculum, and of the two students he was probably the more likely to obtain his qualifications in 1914. The Conjoint Board has now made a concession in that the last year spent at a public school only counts to the student as six months of his curriculum.

(To be continued.)

MOTORING NOTES.

BY C. T. W. HIRSCH, M.R.C.S. ENG., L.R.C.P. LOND.

The New 14-16 h.p. Darraoq Car.

Following the unmistakable tendency that there is towards four-cylinder cars of more moderate power, and of considerably lower price, the Darracq Motor Company, Limited, of Walnut Tree Walk, London, have introduced a new model, which, both in price and design, should meet the present demand. As it will be shown at Olympia in a few days, it struck me that the medical profession visiting the exhibition might appreciate some facts about this car, which is four-seated, of light weight, sufficient power, reasonable speed, and is turned out complete at the moderate figure of £225. Of course, if a firm of no previous reputation brings out a vehicle of original features, the prudent man will think twice before considering a purchase, but in this case the innovation is vouched for by a company with an established name, and seems to me to imply a good deal as to the future policy of Messrs. A Darracq and Company Limited

Now to describe the car both briefly and clearly. The four cylinders have each a bore of 85 mm. and a stroke of 100 mm., and are cast in one piece; the valves are all on one side, so as to be worked by one cam shaft; and this shaft projects, so that if a supplemental ignition is ordered, a coupling can be attached and the commutator

so driven. The valve-lifters are fitted with rollers where they receive the impact of the cams on the two-to-one shaft, and the guides are cast in the upper part of the crank case. Standard ignition is by a high-tension Sims-Bosch magneto, with fixed timing. It is driven by gearing, and the spindle also works the water-circulating pump. The magneto is held by a single nut to the top of the crank case. I prefer a stirrup for holding the magneto to its bed. I found that I was able to undo the nut, but it was very inaccessible and troublesome; undoing a nut underneath a projection and needing contortions of the hand to get at, may also be damaging to the professional look of the practitioner's cuffs. The carburettor is both simple and accessible; the petrol enters the top of the float chamber by gravity, and passes to the jet, which stands up in an open tube, leading to the inlet valves by a throttle, with an automatic air-intake. Through the open lower end of the tube air is sucked, petrol comes up the jet, and the amount that reaches the engine is regulated by a foot-controlled throttle. Slacken one exposed nut and then the jet can be pushed up and withdrawn. If there were not other inducements, and as a matter of fact there are many, this convenient petrol jet would be enough to make me think highly of the car. I have a recollection of once having to take down a carburettor, so as to clear a blocked jet, and, in that case, to get the carburettor off necessitated removing inlet pipes and hot exhaust pipes, so the accessible jet appealed greatly to me. Lubrication is automatic, but without any visible apparatus on the dash. Inside the crank case is a plunger pump driven off an eccentric on the cam shaft, and thus lubricant is supplied to the crank case, gudgeons, and main bearings. Under the crank case is a sump from which the pump feeds and to which all surplus oil is returned. The oil is introduced by a pipe projecting from the crank case, and a float stands out of this pipe from the height of which the quantity of oil can be judged, and the time for replenishing the supply gauged. To make sure that the oil pump is performing its work, a little tap is screwed into the crank case near the carburettor, with the engine running; if the pump is operating, oil will shoot out of the tap when it is opened. The pump can also be fairly easily got at. The chassis, which is of pressed steel, forms the underframe and shield, but in the centre there is an opening through which, standing in a pit under the car, a plug in the lower half of the crank case can be taken out, and then with a long screw-driver the pump can be extracted.

The cooling system is worked by a gear-driven pump, and a large fan behind the gilled tubed radiator further ensures ample cooling. On the trial run of two hundred and odd miles the cooling was ample to enable the engine to develop its full power for very long periods. The trans mission is by a leather-covered cone clutch, the engagement of which is made easy by buffer springs, through a short shaft with squares at each end to a gear box, in which provision is made for three speeds forward and a reverse. These are effected by double-sliding pinions, controlled by one lever working in a gate quadrant. From the gear-box a cardan shaft with a universal joint at either end conveys the power to the live axle. The back axle revolves with the wheels and is encased in a steel sleeve, an enlargement of which forms the differential case, and in this the crown wheel meshes with the bevel at the end of the cardan shaft. The side thrust is taken up by ball-bearings. In the gearbox as well as for the wheels plain bearings are employed. Provision is made for increasing the tension of the clutch spring. Another characteristic is the comfort of the car's suspension, which is the result of semi-elliptic springs in front and three-quarter elliptic at the back. The steering pillar is well raked, and provision is made for closing up the bearing surfaces, so as to avoid play or backlash as they wear. The control is by a foot accelerator, working the throttle in the induction pipe, and it is certainly preferable to a hand-worked control; the only trouble that I had in this particular instance was that the spindle on the mushroom was rather short, and I found it rather a stretch to keep the pedal down. The makers, of course, could easily fit a longer spindle in accordance with the driver's length of limb. An extra control is fitted to a sector attached to the dash, which is useful for starting the engine; an agitator is also attached to the carburettor for flooding, and so obtaining a richer mixture, an advantage for starting, especially in cold weather. Instead of a switch a small button projects on the dash, by

which the electricity is earthed and cut off from the engine. Internal expansion brakes are fitted to the hubs of the rear wheels and a foot-brake of similar design is mounted behind the gear-box. Artillery wheels are supplied with 810 \times 90 tyres.

Messrs. Darracq usually fit a four-seated double phaeton body to this car, but the chassis would do well with a two-seated body and front glass and hood for the practitioner who is his own chauffeur, while with a landaulette body it would make an ideal carriage for the medical man who does not drive himself. The makers had such confidence in the car, or the writer, perhaps in both, that they handed me a new one from stock, with the request that I should take it for a drive without any representative of their firm, and use it for any trial I considered proper. I certainly took them at their word, and though the weather was unfavourable, with three passengers I used it for a holiday tour, over Kentish hills, through London traffic, via Kingston, Staines, Maidenhead, Henley, Beaconsfield, up the 1 in 11 Studley Green Hill, down Cockshoot Corner, and so by Oxford. Blenheim Palace, Shipston-on-Stour, Stratfordon-Avon, Warwick, Leamington, and home by Daventry and Towcester, with a good test for the brakes on West Hill, Highgate. In all it was over a 200-mile run, and as a result I find that this little four-cylinder car has the merits of silence, flexibility, and smooth running, and power enough to ensure a good average speed up hill and down dale. In fact, with four passengers it took many hills of 1 in 14 easily on the second speed, and did a test hill of 1 in 6 without a murmur on the first speed. It seems to meet the requirements of the average medical man who is seeking for a fair-sized car of the orthodox type but only desires to pay a comparatively small sum for possession and upkeep. It is certainly as simple and free from complications as a car can be, and should be inspected by all medical men attending at Olympia in search of a motor.

Chauffeurs and their Liveries.

A recent case at the West London police-court is of interest, as evidence of what chauffeurs may try to obtain by virtue of common custom. In the case in point the owner of a car who had dismissed his driver sued the latter for the return of livery supplied while in the plaintiff's service. The defendant contended that the custom was for the livery to be given to the driver, but the learned magistrate properly held that such custom was not established and made an order for the return of the overcoat in question.

MORTALITY FROM "CONSUMPTION" IN DUSTY TRADES IN THE UNITED STATES OF AMERICA.

We have received from the Government Printing Office at Washington Bulletin No. 79 of the Bureau of Labour, which contains an important report by Frederick L. Hoffman on the mortality from consumption in dusty trades. Whether or not the writer is a member of our profession we are uncertain, but it would appear as though this were the case, for in the present report he refers to his own contributions on tuberculosis and other allied topics to various American medical periodicals and medical societies. But in either case the salient points of this report are well worthy of comment.

The use of the term "consumption" in such a work seems to us unfortunate, for the reader is left to decide for himself whether it is meant to indicate pulmonary tuberculosis exclusively, or whether it applies to all forms of tuberculous disease. From the context, however, we gather that the former is the sense in which the term is employed; and in what follows the term "consumption" will be regarded as synonymous with tuberculous phthisis. In order to determine approximately the loss of life from phthisis in the various occupations, several statistical expedients are resorted to in the United States. Among these the most trustworthy method is obviously that of ascertaining the true rate of mortality-i.e., the number of deaths occurring in every 1000 persons in any particular industry. This is the method adopted by Dr. John Tatham in his successive supplements to the reports of the Registrar-General of England, to which frequent reference is made in the present work. But in America it is seldom employed;

in the first place, because of the want of accurate information regarding the numbers found to be engaged in the several employments at the last census, and in the second place because of want of uniformity in the classification of workers adopted by the several Boards of Health. The expedient most favoured in the United States is that of calculating the proportion of deaths from a particular disease as a percentage of the total deaths at specified periods of life. The result is termed the "proportionate mortality figure," and this has been extensively employed in the present report with the object of utilising the valuable insurance mortality statistics which in America are generally available for the purpose.

In this connexion a warning is desirable against confounding the term "proportional mortality figure" as used in this report with the term "comparative mortality figure" as employed in the supplements to the reports of the English Registrar-General, the latter term having an entirely different meaning. In America the insurance mortality statistics are derived from the experience of a large and representative company which has from time to time published the facts of its experience. The insurance proportional mortality returns, however, obviously indicate a phthisis death-rate which is below the normal, since the figures are affected by medical selection. In other words, the true loss of life from consumption at specified ages would have been higher had no medical selection of the lives been effected. The method of applying the proportional mortality figure to workers at successive ages in the various occupations may be illustrated as follows. At ages 25 to 35 years, out of every 100 deaths from all causes in the United States registration area during the last seven years 31 were from phthisis; the corresponding proportion of deaths in the industrial insurance mortality experience was 71 per cent for grinders, 67 per cent. for compositors, 59 per cent. for upholsterers, and 53 per cent. for potters, &c. The difference between the normal proportional phthisis mortality for the entire area on the one hand, and that of the individual occupations on the other, measures approximately the hazard to health and life in the several industries.

Without attempting to follow the author in his detailed descriptions of occupational mortality, which occupy 240 pages of an octavo volume, we proceed to summarise some of the more interesting of his conclusions. For the purposes of the present investigation careful analysis has been made of nearly 23,000 deaths from all causes occurring among workers of various ages in the principal industries of the United States. Taking together all the occupations for which information is available, the proportional mortality from consumption at all ages above 15 years appears to average 28 per cent. of the mortality from all causes. Among individual industries the proportion ranges from the highest, 37 per cent., in those occupations which are exposed to metallic dust, to the lowest, 24 per cent., in occupations exposed to organic dust. Extending the analysis to divisional periods of life, we find that at ages 15 to 25 the proportional consumption mortality was highest (viz., 50 per cent.) in occupations exposing to the inhalation of animal and mixed fibre dust, and next highest (viz., 47 per cent.) in occupations exposing to metallic dust. In occupations exposing to organic dust it was 41 per cent; to street dust, 40 per cent.; to vegetable fibre dust, 39 per cent.; and to mineral dust, 32 per cent. At ages 25 to 35 the proportional consumption mortality was highest (viz., 57 per cent) in occupations exposing to metallic dust; in occupations exposing to vegetable fibre dust it was 53 per cent; to organic dust and to animal and mixed fibre dust, 50 per cent.; and to street dust, 44 per cent. At ages 35 to 45 it was highest (viz., 43 per cent.) in occupations exposing to metallic dust; in occupations exposing to animal and mixed fibre dust and to vegetable fibre dust it was 40 per cent; to mineral dust, 36 per cent.; to organic dust, 36 per cent.; and to street dust, 35 per cent. At ages 45 to 55 it was highest (viz., 28 per cent.) in occupations exposing to mineral dust; in occupations exposing to metallic dust it was 24 per cent.; to animal and mixed fiore dust and to vegetable fibre dust, 23 per cent.; to organic dust, 22 per cent.; and to street dust, 14 per cent. At ages 55 to 65 it was highest (viz., 16 per cent.) in occupations exposing to mineral dust; whilst in occupations exposing to the inhalation of other irritating kinds of dust it averaged from 11 to 12 per cent. of the deaths from all causes.

With respect to that period of life in which pulmonary

phthisis is most prevalent in America the following particulars will be interesting. In the year 1900 the mortality from all causes among men in specified industries was 15.0 per 1000, and the consumption-rate was equal to 16 per cent. of that mortality. Among men in manufacturing industries the general death-rate was 13.8 per 1000, of which 18.8 per cent. was due to consumption. Among men in agricultural, transportation, and other outdoor occupations the general deathrate was 15.8 per 1000, and the consumption death-rate equalled 9.5 per cent. of the total. By contrasting the consumption mortality in these two groups of employment the enormous waste of human life becomes readily apparent. This will be even more clearly shown if we quote a few particular instances. Thus we read that the census mortality rate from all causes among stonecutters was 14.9 per 1000, 36.2 per cent. of which was due to consumption. Among printers and compositors the general rate was 12.1 per 1000, 36 per cent. of which was credited to consumption. On the other hand, among the strictly outdoor class—i.e., farmers and farm labourers—whilst the general death-rate was relatively high, viz., 17.6 per 1000, the consumption death-rate was only 1.1 per 1000, or 6.3 per cent. of the mortality from all

Adopting the author's estimate of about 32 millions as the number of the American wage-earning population above the age of 15 years, and assuming a consumption death-rate among them of 2·2 per 1000, the number of lives lost by consumption in this section of the population would approximate to 70,000. If by intelligent sanitary inspection and control, especially as regards ventilation, it were possible to eliminate most of the conditions injurious to health in factories and workshops, it is quite reasonable to hope that the consumption death-rate among wage-earners would be reduced to a ratio not exceeding 1·5 per 1000. Such a reduction would mean an annual life-salvage of more than 22,000 lives. The author goes on to calculate, by placing an arbitrary economic value on the net result of a year's life, that the annual financial value of such life-salvage would be colossal.

THE FIFTY-EIGHTH REPORT OF THE INSPECTORS OF LUNATICS, IRELAND.1

THE number of the insane in establishments was on Jan. 1st, 1909, 23,931, this being an increase of 213 upon the number recorded for Jan. 1st, 1908. The increase during 1908 was greater than that which took place in 1906 or 1907. It was, however, 200 less than the average increase for the preceding ten years. The numerical increase at the end of last year appears mainly to be due to the transfer to the asylums of the inmates of the imbecile wards of workhouses. As no certificates of insanity are required for the cases maintained in workhouses the vacancies caused by such transfers are quickly filled up by paupers suffering from the mental decay of old age, and these cases, which were not previously classified as insane, are then for the first time returned amongst the insane inmates of the workhouses, thus swelling unduly the number of the insane under care. During the year 1908, 816 cases were transferred from workhouses to asylums, being over 21 per cent. of the total number of admissions to the latter institutions. The percentage was higher than that of any year since 1904. Unfortunately, these transfers are included amongst the first admissions, and therefore, without the necessary correction, such admissions cannot be accepted as showing the amount of freshly occurring insanity in the community or as affording reliable data on which to draw conclusions regarding the increase or decrease of insanity amongst the population. In 1881 the admissions to district asylums numbered 2592 and in 1908 they amounted to 3798. In the case of the private asylums the numbers for 1881 were 145 and for 1908 they had increased to 269. The increase in the last as compared with the first year of the period amounted in the case of district asylums to 52 per cent. and in the case of the private asylums to 86 per cent. The number of the insane under

care has increased from 250 per 100,000 of the population in 1880 to 547 per 100,000 in 1908. The total number of patients discharged during the year was 1848. Of these, 1401 were discharged recovered, showing an increase of 30 on the number for the previous year. The percentage of recoveries on the admissions was 36.9. The number of deaths during the year was 1417. The death-rate per cent. of the daily average number resident was 7.1. In only 236 cases were post-mortem examinations made, and in two asylums no necropsy was made during the year.

It appears that complaints have recently been made by the medical superintendents of some asylums that the candidates for appointment as attendants and nurses are generally of a lower standard—physically and mentally than those who offered themselves for such posts in former years. It is manifest that to obtain persons physically and constitutionally sound, of good intelligence, and of kindly disposition and temper, it is necessary that the wages offered and the conditions of service should be sufficiently attractive. In so poor a country as Ireland it is not to be expected that the remuneration can be as high as that paid for similar services in some other countries. All that can be asked is that the wages offered to candidates entering the asylum service should not be lower than the usual rate of remuneration for skilled labour in the neighbourhood, and that the conditions of service—including accommodation, food, and hours of duty—should be made as attractive as possible. It appears, however, that although in some asylums the wages and conditions of service have been greatly improved, in others they remain as they were many years ago, and are below the average now paid for similar labour elsewhere.

We notice with regret that the inspectors have in a large number of the asylums to report on the defective character of the accommodation. In one asylum the wings of the institution provide very cheerless and prison-like accommodation. The day rooms are insufficient for the numbers who sleep there, and consequently some of the women have to sit in the flagged corridor during the day. In another asylum the want of day-room accommodation is especially noticeable; in fact, there is an almost total absence of day-rooms, the great majority of the patients having to be crowded together in corridors. In another the number resident is considerably in excess of the number for whom there is proper accommodation, and the overcrowding is so great that beds have in some cases to be laid down in corridors. In yet another the institution is so overcrowded that a great number of the males have no indoor accommodation in which to spend their days. The inspection of the workhouse accommodation for the insane has revealed conditions which are in several cases even more unsatisfactory.

Looking Back.

PROM

THE LANCET, SATURDAY, Oct. 29th, 1881.

To the Editor of THE LANCET.

SIR,—I have searched all the books to which I have access on diseases of the eye, but cannot meet with a description of any case attended with symptoms similar to the following, which has been under my care for the last fortnight, and an account of which I now send, for insertion in your much-esteemed Periodical, in the hope that some of your ingenious correspondents may be induced to favour the public with their opinion on it, and at the same time make known whether experience or reading has furnished them with any example of the kind, adding to their account a statement of the medical treatment and results.

John Frost, carrier, aged 48, of stout make and rather plethoric habit, on his return from Exeter market, was seized with such a dimness of sight that he could not discern any object at the distance of a few yards, and was unable to keep on the road without holding by the end of his cart, though it was only about three o'clock P.M., and the day quite fine and clear. Before reaching his home, however, he found that on closing, or covering, either eye with his hand, he could see sufficiently well with the other. I was sent for to his house next morning, and found that he could scarcely perceive even

¹ The Fifty-eighth Report of the Inspectors of Lunatics (Ireland) for the Year ending Dec. 1st, 1908. Dublin: Printed for His Majesty's Stationery Office by Alexander Thom and Co., Abbey-street.

the lines of a book when both eyes were open, but that on closing either of them he could read distinctly every word.

These symptoms were accompanied with considerable pain in the forehead, and a full, quick, and rather hard pulse; being a stout man, I took from the arm about 24 ounces of blood, gave him some compound colocynth pills, with a grain of calomel in each; two to be taken every three hours till the bowels were freely opened, and directe i a blister to be applied to the back of the neck at bedtime. Next day I found the pulse softer, the pain of the head gone, but no alteration in the sight, either for the better or worse. In this state he continues, entirely free from pain, but still under the necessity of wearing a bandage over one eye, without which he cannot even see to walk. Errhines, and a little spt. etheris sulphurioi, applied to the eyes twice a day since the application of the blister, always afford him temporary benefit. I cannot discover the slightest irregularity in the motions of the iris; the pupils seem neither more dilated nor contracted than they ought to be; the humours appear perfectly transparent and healthy, and there are no traces of either irritation or inflammation to be perceived. Whether the above anomaly portends the commencement of amaurosis, or is to be considered merely as resulting from a temporary weakness or relaxation of nervous power, I shall leave to the determination of the learned; but I cannot help thinking, that it strongly favours the opinion of those who advocate the existence of some fluid essence circulating in the course of the nerves, the influx of which, in this case, seems insufficient for supporting the action of both eyes at once, but enough when directed upon one of these organs to render vision complete.

I am, Sir, your most obedient servant,
WILLIAM REED, Surgeon.

Kentisher, near Collumpton, Devonshire, October 20th, 1831.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 8180 births and 3771 deaths were registered during the week ending Oct. 23rd. The annual rate of mortality in these towns, which had been equal to 12.9 and 12.2 per 1000 in the two preceding weeks, further declined to 12.0 in the week under notice. During the first three weeks of the current quarter the annual death-rate in these towns averaged 12 · 4 per 1000, and in London during the same period the rate did not exceed 11.9 per 1000. The lowest annual rates of mortality recorded in the 76 towns last week were 5·2 in West Hartle-pool, 5·6 in Ipswich, 5·7 in Walthamstow, and 6·5 in Willesden; the rates in the other towns ranged upwards, however, to 19·2 in St. Helens, 19·3 in Huddersfield and in Middlesbrough, 19 5 in Great Yarmouth, and 20 6 in Merthyr Tydfil. In London the recorded death-rate last week did not exceed 11.5 per 1000. The 3771 deaths in the 76 towns last week showed a further decline of 74 from the numbers returned in the two preceding weeks, and included 312 which were referred to the principal epidemic diseases, against numbers declining steadily from 849 to 387 in the eight preceding weeks; of these 312 deaths, 142 resulted from diarrhea, 46 from diphtheria, 36 from measles, 33 from scarlet fever, 28 from whooping-cough, 25 from "fever" (principally enteric), and 2 from small-pox. The 312 deaths from these epidemic diseases last week were equal to an annual rate of $1\cdot 0$ per 1000, against rates declining in the eight preceding weeks from $2\cdot 7$ to $1\cdot 2$. No death from any of these epidemic diseases was registered last week in Cardiff, Croydon, Willesden, Walthamstow, or in 12 other smaller towns; the annual death-rates therefrom ranged upwards, however, to 2.8 in Salford, 3.0 in Hull and in Hauley, and 3.4 in Barnsley. The deaths attributed to diarrhee in the 76 towns, which had declined in the eight preceding weeks from 675 to 208, further fell last week to 142, but caused annual death-rates ranging upwards in the several towns to 1.6 in St. Helens, 1.7 in Wigan and in Hull, and 1.9 in Devonport and in Tynemouth. The deaths referred to diphtheria, which had been 28 and 51 in the two previous weeks, declined again last week to 46; they included 11 in London and its suburban districts, 6 in Manchester and Salford, and 3 in Hull. The 36 fatal cases of measles were fewer by 4 than

the number in the previous week, but showed proportional excess in Birkenhead and in Hornsey. The 33 deaths from scarlet fever showed a further decline from those returned in the two previous weeks; the 4 recorded in Blackburn were equal to an annual rate of 1.5 per 1000. The 28 fatal cases of whooping-cough exceeded those in the previous week by 1. Of the 25 deaths referred to "fever," 2 were returned in Wolverhampton, in Liverpool, and in Leeds, and 7 in London and its suburban districts. The 2 fatal cases of small-pox occurred in Hull. The number of scarlet fever patients under treatment in the Metropolitan Asylums and London Fever Hospitals, which had steadily increased in the eight preceding weeks from 2347 to 2810, had declined to 2799 on Saturday last; 345 new cases of this disease were admitted to these hospitals during last week, against 324 and 371 in the two preceding weeks. The Metropolitan Asylums Hospitals contained 2 small-pox patients on Saturday last. Of the 1067 deaths registered in London last week, 174 were referred to pneumonia and other diseases of the respiratory system, against 186 and 167 in the two preceding weeks, and were 25 below the corrected average number in the corresponding week of the five years 1904-08. The causes of 37, or 1.0 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death registered during last week were duly certified in Bristol, West Ham, Bradford, Newcastle-on-Tyne, Portsmouth, and in 50 other smaller towns; the 37 uncertified causes of death in the 76 towns last week included 7 in Liverpool and 6 in Birmingham.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 886 births and 470 deaths were registered during the week ending Oct. 23rd. The annual rate of mortality in these towns, which had been equal to 12.0 and 12.8 per 1000 in the two preceding weeks, further rose to 13.1 in the week under notice. During the first three weeks of the current quarter the annual death-rate in these Scotch towns averaged 12.6 per 1000, and exceeded by 0.2 the mean rate during the same period in the 76 large English towns. The annual death-rates last week in these Scotch towns ranged from 10.2 and 10.4 in Paisley and Edinburgh, to 14.8 in Glasgow and 17.0 in Perth. The 470 deaths from all causes in the eight towns last week showed a further increase of 14 upon the numbers returned in the two previous weeks, and included 54 which were referred to the principal epidemic diseases, against 45 in each of the two preceding weeks. These 54 deaths were equal to an annual rate of 1 5 per 1000, against a mean rate of 1.0 from the same diseases last week in the 76 English towns. The 54 deaths from these diseases in the Scotch towns last week included 28 from diarrhoea, 11 from diphtheria, 5 from measles, 5 from whooping-cough, 3 from scarlet fever, and 2 from "fever," but not one from small-pox.. The deaths attributed to diarrhoea, which had been 18 and 15 in the two previous weeks, rose to 28 last week, and exceeded the number in any week since the early part of September; 14 occurred in Glasgow, 5 in Dundee, 3 in Aberdeen, and 2 in Edinburgh and Leith. The 11 deaths from diphtheria were within one of the number returned in each of the two preceding weeks, and included 6 in Glasgow and 3 in Edinburgh. The 5 fatal cases of measles showed a decline; 3 were returned in Glasgow and 2 in Edinburgh. The 5 deaths from whoopingcough exceeded the numbers in recent weeks, and included 2 in Greenock; and the 3 fatal cases of scarlet fever occurred in Glasgow. The 2 deaths referred to "fever" were fewer than in any recent week, and were both certified as cerebro-spinal meningitis; 1 each was returned in Glasgow and in Edinburgh. The deaths referred to diseases of the respiratory system in the eight towns, which had been 59 and 58 in the two preceding weeks, rose to 84 last week, and exceeded by 28 the number in the corresponding week of last year. The causes of 17, or 3.6 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 1.0 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated

population of rather more than a million, 613 births and 325 deaths were registered during the week ending Oct. 23rd. The mean annual rate of mortality in these towns, which had been equal to 15·1 and 15·2 per 1000 in the two preceding weeks, declined to 14·8 in the week under notice. During the first three weeks of the current quarter the annual death-rate in these Irish towns averaged 15.0 per 1000, whereas the mean death-rate during the same period did not exceed 12.4 in the 76 largest English towns and 12.6 in the eight principal Scotch towns. The annual deathrate during last week was equal to 15.2 in Dublin (against 17.5, 16.8, and 16.0 in the three preceding weeks), to 12.9 in Belfast, 21.2 in Cork, 16.9 in Londonderry, and 19.5 in Waterford; the mean rate in the 16 smallest Irish towns was equal to 14.5 per 1000. The 325 deaths from all causes in the 22 town districts last week showed a decrease of 9 from the numbers in the previous week, and included 22 which were referred to the principal epidemic diseases, against 42, 37, and 29 in the three preceding weeks; these 22 deaths were equal to an epidemic diseases, against 42, 37, and 29 in the three preceding weeks; these 22 deaths were equal to an annual rate of 1.0 per 1000, corresponding with the rate from the same diseases last week in the 76 English towns. The 22 deaths from these epidemic diseases in the Irish town districts last week included 12 from diarrhea, 5 from whooping-cough, 2 from diphtheria, and 1 each from measles, scarlet fever, and "faver" but not one from small-nox. The deaths and "fever," but not one from small-pox. The deaths attributed to diarrhoea in the 22 towns, which had been 22 and 14 in the two previous weeks, further declined to 12 last week, and included 5 in Belfast and 2 both in Dublin and in Cork. The 5 fatal cases of whooping-cough were within one of the number in the previous week, and included 2 both in Cork and in Limerick and 1 in Dublin. Of the 2 fatal cases of diphtheria, 1 occurred in Ballymena and 1 in Clonmel. A fatal case of typhus was registered in Dublin. The 50 deaths referred to pneumonia and other diseases of the respiratory system last week in the 22 towns corresponded with the number returned in each of the two preceding weeks. The causes of 14, or 4.3 per cent., of the deaths in the 22 town; last week were not certified by a registered medical practitioner or by a coroner; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 1.0 per cent., but in the eight Scotch towns the proportion was equal to 3.6 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified: -Fleet-Surgeons: M. L. B. Rodd to the Niobe, and to the Kent on recommissioning; E. R. D. Fasken to the Argonaut. Staff-Surgeons: J. O. Rowan to the Mars; P. H. Boyden to the Fisgard; and E. T. P. Eames to the Endymion. Surgeon: E. Cameron to the Argonaut.

ROYAL ARMY MEDICAL CORPS.

Colonel Maclean officiates as Principal Medical Officer, 8th (Lucknow) Division, vice Surgeon-General Ellis, on leave. Colonel Anderson has reverted to his permanent appointment as principal medical officer, Allahabad and Fyzabad Brigades.

Lieutenant-Colonel G. E. Hale, D.S.O., has been appointed medical inspector of recruits in the Eastern Command, and Lieutenant-Colonel T. Du B. Whaite has been appointed to the Eastern Command. Major C. K. Morgan has been

appointed to the Belfast District for duty.

Captain Francis S. Irvine, from the Seconded List, is restored to the establishment (dated Oct. 13th, 1909).

Indian Medical Service

Major H. G. Melville officiates as Principal, Medical College, Lahore, vice Major Sutherland, going on one year's leave; and Captain Macgilchrist officiates as Professor of Materia Medica, Lahore Medical College, vice Major Melville. The services of Major Smith are placed permanently at the disposal of the Punjab Government. Captain E. C. Hepper has been appointed to the substantive medical charge of the 51st Sikhs (Frontier Force), vice Captain H. Halliday. Captain G. W. Maconachie has been appointed to the sub-

Captain W. C. Hamilton. Captain R. F. C. Talbot has been transferred to the temporary half-pay list from July 24th.

TERRITORIAL FORCE.

Royal Army Medical Corps.

3rd Lowland Field Ambulance: Lieutenant James H. H. Pirie to be Cuptain (dated Oct. 1st, 1909).

1st South Midland Field Ambulance: Lieutenant Hans Frederick William Boeddicker, from the 2nd South Midland Field Ambulance, Royal Army Medical Corps, to be Lieutenant (dated Sept. 29th, 1909).

1st North Midland Field Ambulance: Captain William J.

Reid to be Major (dated April 19th, 1909).

THE PHYSICAL EFFECTS OF THE ALLOWANCE FIELD SERVICE RATIONS.

An officer with 20 volunteers of the 1st Battalion Loval North Lancashire Regiment, none of them specially selected, have recently been the subject of an experiment for the purpose of determining the quality and quantity of the field service rations in relation to the clothing and equipment of the soldier. The company were instructed to march for 12 days a distance of at least 14 miles under service conditions. The valies equipment with field service kit was carried together with 150 rounds of ball ammunition, weighing altogether, with rifle, more than half hundredweight. For the first six days the food consisted wholly of biscuit and preserved meat and vegetables. Subsequently fresh meat and bread were issued in lieu of preserved rations, and this was followed by a noticeable improvement in the physique and spirits of the men. A report will be made for the information of the Army Council by Lieutenant-Colonel Melville, R. A. M.C.

Correspondence.

"Audi alteram partem."

THE DANGERS OF THE DRY SHAMPOO.

To the Editor of THE LANCET.

SIR,-My absence in America has prevented me from following in detail the proceedings arising out of the accident in July last in consequence of the use of carbon tetra-chloride as a "dry shampoo." I learn, however, on my return that by what has since taken place the public and the trade concerned have been duly warned of the dangerous character of this particular chlorinated compound, carbon tetrachloride. I learn further from the answer returned yesterday by the Home Secretary to a question by Sir William Collins that "the matter is receiving his serious attention and the question whether legislation ought to be undertaken will be fully considered."

I should like at this stage to point out a further consideration that in my opinion is of sufficient gravity to call for prompt decision as to the prohibition or not of the use of carbon tetrachloride and similar poisons for toilet purposes. Carbon tetrachloride, chloroform, ethylene chloride, ethylidene chloride, &c., are all more or less anæsthetic and stimulant, just as in lesser degree ether and alcohol are anæsthetic and stimulant. In my experience the physiological equivalence between chloroform and alcohol is approximately 100 to 1, and a few drops of chloroform or of carbon tetrachloride rubbed in the palm of the hand and inhaled as a "refresher" or a "sedative," are quite as effective, pleasant, and insidious as a glass of brandy. More or less carbon tetrachloride is necessarily inhaled in the course of a "dry shampoo," and there are in existence numerous other chlorinated compounds of similar properties. Chloroform is scheduled as a poison. Carbon tetrachloride, which is more poisonous than chloroform, and allied substances that are more or less poisonous, are not so scheduled.

Ought the use of these substances to be left at the discretion of the more or less enterprising hairdresser? Or ought not the public to be protected by the scheduling as poisons of substances that are more dangerous to life than chloroform and more insidious than alcohol? According to the evidence given by one of the witnesses at the inquest held last July the number of persons taking the dry shampoo with carbon tetrachloride averaged between 90 and 100 per stantive medical charge of the 73rd Carnatic Infantry, vice day at one establishment alone (or between 20,000 and

30,000 for the year, with the total consumption of 14 tons I am, Sir, yours faithfully,
A. D. WALLER. of the liquid).

Physiological Laboratory, University of London, Oct. 21st, 1909.

EDRIDGE-GREEN'S THEORY OF VISION AND COLOUR VISION.

To the Editor of THE LANCET.

SIR,-The question of the meaning of the structure of the retina is the latest one in physiological optics—i.e., from the subjectival standpoint held by E. Hering, Mach, and myself. As Edridge-Green has found for the distribution of the visual purple, so I, Hering, Hess, Garten, and others, have found only gradual quantitative differences in the sight between the foveal and extrafoveal area. The phenomenon of Purkinje, the alteration of optical white equations by the state of light- and dark-adaptation, the colourless interval for spectral lights of increasing intensity, the different phases of the after-image,—all these subjective reactions exist, not only in the extrafoveal, but also (only gradually diminished) in the foveal region. The analogy between this behaviour and Edridge-Green's objective statement about the visual purple

As principia, I believe that it is absolutely necessary for the classification of colours to start with sensation analyses, from the statement of the simple effects by some definite but individually different lights, homogeneous or mixed. It is also necessary to note the changes produced in each case by varying states of light- and dark-adaptation. We must ascertain the position of pure green, pure yellow, pure blue in the spectrum, and of pure red in mixed light, and of the corresponding neutral points in the colour-blind. It is totally wrong to conclude from the constitution of physical stimuli (composition, wave-length) that the physiological effect or the psychological sensation are similarly constituted. Therefore all colour theories based on light mixture (colour mixture is a very bad expression), as the theory of Young-Maxwell-Helmholtz, A. Fick, J. v. Kries, are fallacious.

Hering holds that for the regular cases of colour blindness there is a defect of red-green or yellow-blue or red-yellow-green-blue perception. The antagonistic correlation between red and green and yellow and blue is founded in the nervous apparatus; the regular cases of colour blindness are therefore nervous anomalies. On the other side, I believe that alone or combined with a nervous anomaly there are many cases in which photo-chemical anomalies in the retina exist. I believe that the visual purple could be one of the photo-chemical stimulus-transformers for the nervous apparatus, especially the stimulus-transformer for the white sensation in the dark adapted eye. There may be a large number of such photo-chemical substances, at least six (for red, yellow, green, blue, and two for white sensation), the absorption spectra of which coincide partially, for p.e. the point of pure green varies according to the state of adapta-tion of the eye. As a pupil of Hering I may say that Hering has always objected to the association of his theory with the photo-chemical processes of the retina as it is only concerned with the central processes.

I am, Sir, yours faithfully,

A. VON TSCHERMAK,

Oct. 25th, 1909.

Professor of Physiology in the University of Vienna.

THE TREATMENT OF ADDER BITES.

To the Editor of THE LANCET.

SIR,-The recent correspondence on adder bites has prompted me to report a case which came under my care last year.

A boy, aged 11 years, was brought to me by his mother on July 15th, 1908, at 1.10 P.M., the history being that he had been bitten by a grass snake which he had caught the previous day, and which he had handled freely until 12.55 P.M. on the 15th, when it had bitten him. When I examined him, only one-quarter of an hour after he had been bitten, I found a small pin-prick wound on the dorsum of the right index finger from which a little serum was exuding. The skin around the wound was discoloured, and the whole finger and dorsum of the hand were very cedematous. There menon is found with small portions of the retina, and

was slight lymphangitis of the forearm, and the axillary glands formed a lump of the size of a pigeon's egg. The boy was evidently in great pain. He was pale; his pulse was 60 and of very low tension, and his temperature 98 2° F. He had vomited twice on the way to my house. I asked the mother to fetch the snake, which turned out to be a female viper, and in the meantime put on a tourniquet, and I made a deep incision an inch long through the site of the bite. The tourniquet was then slightly loosened and the patient sucked the wound for half an hour. As the boy had fainted twice and again vomited I gave him 1-100th grain strychnine hypodermically, dressed the wound with permanganate of potash crystals and wet boracic lint, and having removed the tourniquet I ordered that he should be taken home and put to bed. He was there wrapped in blankets and kept warm with hot-water bottles, brandy being administered in drachm doses every half hour until 5.30 P.M., when I visited him. He was then in much pain, the whole hand and arm greatly swollen, and the axillary glands so much enlarged that the arm could not be adducted to the side. The glands in the anterior triangle were also enlarged and tender. The pulse was 80 and very soft; his temperature was 99°. I stopped the brandy and gave another 1-100th grain strychnine, together with 1-12th grain morphia. At 7 P.M. the swelling had slightly decreased, but there was still much pain. His pulse was 48, low tension, and his temperature 100°. 20 cubic centimetres of Burroughs and Wellcome's polyvalent antivenom serum were injected into the flank.

At midnight the condition was as before, and as the patient complained greatly of pain in the arm and also at the seat of inoculation I gave him 10 grains of Dover's powder. On the following morning the boy was slightly more comfortable, the arm was less swollen but much discoloured, the glands had not decreased in size, and the whole of the right side of the thorax resembled a large black bruise. The pulse was 72, normal tension, and the temperature was 98.4°; the wound looked dirty and was discharging much clear serous fluid. I therefore ordered him to use a hand-bath thrice daily, consisting of one drachm of tincture of iodine to a pint of hot water. From this moment the swelling and glandular enlargement quickly subsided and the wound became healthy; the discolouration on the chest-wall persisted, however, for several days. It is difficult to say from a single case whether any benefit follows the use of antivenom serum, but I am inclined to agree with Dr. Sapwell that it certainly does no harm.

The points of interest in the case were: (1) the rapidity of the glandular swelling; (2) the collapse as evidenced by the low tension of the pulse, together with vomiting and fainting; (3) the extreme discolouration of the chest wall; and last, but not least, the adder's tractability during the first 24 hours of its captivity. This may, I think, be accounted for by the fact that she "struck" several times at the boy's boots while he was capturing her, and that she had thus more or less exhausted her stock of venom.

I am, Sir, yours faithfully,
MAURICE AMSLER, M.B., B.S. Lond. Eton, Oct. 23rd, 1909.

MALARIA TREATED WITH INJECTIONS OF QUININE.

To the Editor of THE LANCET.

-In THE LANCET of Sept. 11th Dr. G. W. Young quotes three cases of malaria treated with injections of quinine, apparently being under the impression that this is a new form of treatment. I would point out that not only is this method fully described in Sir Patrick Manson's "Tropical Diseases," but also that several thousand injections are given during the year in India, as it is a favourite method of treating malignant cases, especially in the army. —I am, Sir, yours faithfully, A. H. SAFFORD, Captain, R.A.M.C.

Fyzabad, India, Sept. 26th, 1909.

THE BENHAM TOP.

To the Editor of THE LANCET.

SIR,—In reply to Mr. C. E. Benham's letter in THE LANCET of Oct. 23rd, I may say that the fact which I have discovered is that the Purkinje phenomena.

this should be so if the explanation of the Purkinje phenomenon which I have given be the correct one. Every acute observer knows that as the day progresses and twilight approaches reds become darker and darker, and greens, blues, and violets become brighter. This is the Purkinje phenomenon. The answer to the question is that the increased sensitiveness of a portion of the retina to the green rays cannot be evident until it is stimulated by light. The three black lines do not stimulate it. The portion of the retina on which the image of the black disc falls becomes because of the altered photo-chemical action more sensitive to the green. When the top revolves the image of the first part of the white half of the disc is formed on this portion of retina and stimulates it, with the exception of the first three black lines. These black lines therefore appear red through This effect is only momentary. As the top revolves the retina becomes more and more sensitive to the red end of the spectrum, and so when the light is suddenly cut off by the three last black lines the portion adjacent to them becomes blue from contrast, the exact colour depending on the light adaptation produced.

I am, Sir, yours faithfully, Hendon, Oct. 23rd, 1909.

F. W. EDRIDGE-GREEN.

CHROMIDROSIS.

To the Editor of THE LANCET.

SIR, -On p. 1221 of the last issue of THE LANCET appears a reprint of an article published in your columns on Oct. 22nd, 1831, in which an account is given of a case of "The Morbid Transpiration of Blue Colouring Matter through the Skin.' The case is a very good example of a very rare cutaneous affection, now known as "chromidrosis." The first case on record seems to have been one described by Yonge of Plymouth in the year 1709, and from time to time other similar cases have been recorded. It is probable that two different conditions have been confounded under the same name; in one of these the coloured excretion is undoubtedly sweat, for it has been seen to be excreted directly under observation. To this class those cases belong in which the colouration is rapidly formed, but there is another group in which a powdery greasy deposit forms on the skin. The cases in this latter class are probably examples of a coloured sebaceous secretion, for the pigmentary matter cannot be easily removed by means of water, but it is easily got rid of by ether or spirit, and it is readily proved to be composed largely of fatty material. In these cases the excretion is more gradual.

As to its etiology we know little, though here it may be mentioned that some cases of pigmentation of the skin are certainly factitious, as in the well-known epidemic at Brest. where the pigment appeared on the superficial surface of a layer of varnish with which the face had been painted. Of the genuine cases of chromidrosis it is worthy of note that the large majority are women; in one series 41 cases out of In most of the cases the patients have been young unmarried women, though in one instance the patient was 57. There seems little doubt that a neurotic temperament is a great predisposing cause, and various neurotic manifestations have been described in many of the instances. The chief concurrent symptom appears to be chronic and obstinate constipation, and it has been recorded that in some cases the amount of colouration present definitely varied with the degree and duration of the constipation. Sometimes it varies at different times of the day, and there seems some reason to think that some relation exists between it and menstruation, for it has been seen to be more wellmarked just before a catamenial period, diminishing in severity after it.

As to the exact pathology of the condition, there is not much to be said, but as in some cases at least the pigment has given the chemical reaction of indigo. it is not improbable that the condition is sometimes caused by the absorption of indican from the alimentary canal. Stott has described two cases in one family who suffered from pink perspiration sufficient to stain the clothes; in these cases he isolated a yeast, but it is probable that these cases belong to an entirely separate class. The case reported in THE LANCET in 1831 was in a girl of 16 years, and the pigmentation was of a beautiful blue colour. Curiously the account does not mention whether the patient suffered from constipation or not.

The treatment to be followed in these cases is practically limited to relieving any constipation that is present and correcting any menstrual irregularity. If there is any foundation for the idea that the colouration is due to the absorption of decomposition products from the alimentary canal, it is clear that treatment directed to ameliorating the bacterial condition of the bowel would be likely to be followed by an improvement in the condition of the skin. ondition of the sam.

I am, Sir, yours faithfully,

F.R.C.S.

Oct. 25th, 1909.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

FOLLOWING the example of older universities honorary degrees have been conferred upon a number of gentlemen and one lady eminent in science, literature, statesmanship, medicine, and other walks of life. The ceremony was to have taken place when the new buildings were opened by the King last July, but it was decided that the two functions should be separated. The ceremony on Oct. 20th was of sufficient importance to stand on its own basis. The degrees were conferred by the Vice-Chancellor, Alderman Beale, in the absence of the Chancellor, Mr. Chamberlain. The customary oration was made by the Principal. Sir Oliver Lodge, in making the various presentations. The six honoured members of our profession were: Sir Richard Douglas Powell, Bart., President of the Royal College of Physicians of London; Mr. H. T. Butlin, President of the Royal College of Surgeons of England; Dr. J. S. Haldane, Reader in Physiology to the University of Oxford; Professor B. C. A. Windle, President of University College. Cork; Mr. C. S. Tomes, the distinguished dental surgeon; and Dr. Arthur Shadwell, the well-known writer on economics. The other honorary graduates were: The Chancellor (in absentia), Mr. W. N. Atkinson (H.M. Inspector of Mines for South Wales), the Right Hon. A. J. Balfour, the Bishop of Birmingham, Professor Bosanquet, Mr. Andrew Carnegie, Sir William Crookes, Mr. Maurice Fitzmaurice, C.M.G., Sir Archibald Geikie, the Right Hon. R. B. Haldane, Dr. J. Rendel Harris, Sir Charles Holcroft, Bart., Mr. G. J. Johnson, Sir Alexander Kennedy, Professor Sir Joseph Larmor, the Right Hon. Walter Long, Professor Gilbert Murray, Sir William Ramsay, Lord Rayleigh, Professor Rutherford, Mrs. Sidgwick, Lord Strathcona and Mount Royal, Professor Silvanus Thompson, Professor Tilden, Sir J. J. Thomson, Dr. T. H. Warren (President of Magdalen College, Oxford), and Viscount Wolverhampton.

City And Society.

In the annual report of this society which has just been issued the question of cooperation with the hospitals has been considered, especially with regard to the better means for distributing hospital tickets and the method of dealing with out-patients. In conjunction with representatives from the chief hospitals the method of advancing the following principles has been discussed-viz., (1) the elimination of applicants well able to pay for medical assistance; (2) discrimination in the number of those whose ailments would be more suitably treated by a provident dispensary, the Poor-law, or some other agency. It was decided, as a practical start, that, when possible, this society should appoint an almoner to attend at one of the hospitals and take charge of such cases as may be referred by the medical staff as being cases which could be attended to efficiently at home or by some other institution.

Oct. 26th.

WALES.

(FROM OUR OWN CORRESPONDENT.)

Additions to the Cardiff Infirmary.

WHEN the Cardiff Infirmary was founded in the year 1837 the population of the town was a little over 10,000. In the early days of the institution about 80 in patients and 1000 out-patients were dealt with. By 1880 these numbers had increased to 500 and 7000 respectively and the population of the town was considerably over 80,000. It was therefore decided to erect new buildings, and in 1884 the present

buildings were opened with accommodation for 108 patients. The rapid increase in the size of Cardiff, where in 20 years the population was doubled, together with the large increase in the population of the surrounding colliery districts, has necessitated further enlargements of the institution in which there is at the present time accommodation for 194 patients. When it is remembered that the infirmary patients. serves not only the town of Cardiff but a population greater in the aggregate than Cardiff itself dwelling in the Rhondda, Aberdare, and Merthyr valleys it is not surprising to find that the number of patients seeking admission far outnumbers the accommodation available. It became, therefore, advisable some two years ago to erect an additional wing to accommodate 78 beds, and the estimated cost of £30,000 was contributed within nine months of the appeal for it having been made. The foundation-stone of the new wing was laid on Oct. 20th by Mrs. John Nixon, who has contributed 10,000 guineas for the endowment of one ten-bed ward. It is gratifying to find that not only has the entire cost of the new building been provided, but a sufficient sum has already been contributed to maintain nearly one half of the additional 78 beds, and before the completion of the building it is confidently anticipated that many more beds will be endowed.

Housing in Monmouthshire.

The sanitary condition of the colliery districts of Monmouthshire has received a great deal of attention from the medical inspectors of the Local Government Board during recent years, but in spite of the recommendations which from time to time have been made by the Board to the various district councils concerned very little improvement appears to take place in the housing conditions. A report has recently been made by Dr. D. Rocyn-Jones, the county medical officer of health, to the sanitary committee of the county council upon the conditions which prevail in Abersychan, a district with about 20,000 inhabitants adjoining Pontypool. The story which has been related of other parts of the county is repeated with regard to Abersychan: houses are built back to back, or, worse still, back to earth, without damp courses and without proper rainwater gutters, so that dampness of the dwelling is doubly ensured; cellar dwellings and basement houses which it is impossible to ventilate properly are still in occupation, and in some instances overcrowded. The district council has been sufficiently progressive to appoint a lady health visitor, but she must find the difficulties of her work very considerably increased in the presence of the large number of structural defects which are enumerated in Dr. Rosyn-Jones's report.

Barry Accident Hespital.

The urban district council of Barry has provided for the inhabitants of that town not only the ordinary municipal institutions such as public slaughter-houses, a refuse de-structor, and isolation hospitals, but for some years has supported out of the rates a small accident hospital. Until recently the premises used for this purpose were an ordinary dwelling house slightly altered to suit the particular purpose to which it was put, but there has now been erected a special building suitably arranged and well equipped so that the usefulness of the institution will be very much increased. In the old building the surgical staff included a few of the medical practitioners in the town who gave their services without any remuneration, but after much discussion on the subject the district council has now decided that the whole of the medical men in the town shall be on the staff of the new hospital, four being on the rota for four months. It is proposed that each shall be paid an honorarium of £10. Oct. 26th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Late Professor D. J. Cunningham's Library.

IT was intimated at the last meeting of the Edinburgh University Court that the late Professor Cunningham had by his trust deposition and settlement directed his trustees to make over to the University of Edinburgh all his medical and scientific books to form the nucleus of a library for the anatomical department.

The Liston Victoria Jubilee Prize.

The Royal College of Surgeons of Edinburgh have awarded

Liverpool. The prize was awarded by the council to the Fellow or Licentiate of the College "for the greatest benefit done to practical surgery since 1905."

The Teaching of Surgery in Edinburgh.

The University Court has appointed Professor H. Alexis Thomson, professor of surgery in the University, a lecturer and examiner in clinical surgery. This is the continuance of the arrangement made during the later years of Professor J. Chiene's tenure of the chair of systematic surgery. By the older arrangement the holder of that chair, although he had wards in the Royal Infirmary, was not allowed to teach clinical surgery. This curious rule was the survival of an old order of things which should have been broken through long before it was. The chains which bind the Scottish universities are seen in the necessity to formally appoint the professor of systematic surgery to a lectureship of clinical surgery to make his wards available for clinical instruction.

The Royal (Dick) Veterinary College, Edinburgh.

For some time past a scheme has been on foot for the transference of the Royal (Dick) Veterinary College, Edinburgh, from the premises it has occupied in Clyde-street for many years. These premises have long been inadequate for the modern developments in the teaching of veterinary medicine, but the difficulty in finding a suitable site for the school and the want of funds have been a heavy drag upon those who were interested in the efficiency and development of the College. It has just been announced, however, that the Scottish Education Department had decided to recognise the College as a central institution under the Education Act of 1908 and to provide £25,000 towards the cost of new buildings, a similar amount requiring to be raised locally. It is intimated that a site which has been spoken of for some time as suitable, and which is situated at the north-east corner of the Meadows, has been secured and plans of the proposed buildings have been prepared. The site is conveniently near the University and the medical buildings. It is hoped that the requisite money will soon be found for a scheme which is so thoroughly deserving of generous support.

A Memorial to Professor Liston.

A memorial window to Professor Robert Liston, who died in 1847, has been unveiled in the parish church of Ecclesmachan, his birthplace, by Professor Alexis Thomson. The window is the gift of members of the great Scottish surgeon's family and of members of his profession.

The Fate of Sidlar Sanatorium.

A meeting of the directors of the Sidlaw Sanatorium was held on Oct. 21st, when the position brought about by the intimation that most, if not all, of the directors contemplated resigning was under review. There was a full attendance, and it was resolved to hold a meeting of the supporters of the institution next month, when its whole affairs will be discussed and future action resolved upon. It is understood that for several years the institu-tion has been carried on at a considerable loss, the deficiency until now being met by one of the directors, who has specially interested himself in the institution. financial position is said to have suffered through the late agitation for the municipalisation of the sanatorium, and the situation with regard to its maintenance and continuance under its present constitution has reached an acute stage.

Handsome Gift to Montrose Infirmary.

A special meeting of the managers of Montrose Asylum and infirmary board was held in the town buildings on Oct. 21st. The treasurer submitted a letter from Mrs. Wyllie, 3, King's gardens, Hove, Brighton, intimating a donation to the funds of the infirmary of £5000 in memory of her husband, who was a native of Montrose. convener of the infirmary house committee moved that they record their heartiest thanks for the gift. It was the largest donation the infirmary had ever received, and the quiet and unostentatious way in which it had been made added to its value. A number of years ago they had a bequest from Dr. David Wyllie, and now they had the widow of a brother remembering them in that way.

The New Principal of the University of Aberdeen.

The King has been pleased, on the recommendation of the Secretary for Scotland, to approve the appointment of the Rev. George Adam Smith, M.A., D.D., LL.D., Professor of Old Testament Language, Literature, and Theology at the United the Liston Victoria Jubilee prize to Mr. Robert Jones of | Free Church College, Glasgow, to be Principal of the University of Aberdeen, to fill the vacancy occasioned by the death of the Very Rev. John Marshall Lang, D.D. The new Principal is a son of Dr. George Smith, C.I.E., at one time editor of the Friend of India. He was educated at the Royal High School, Edinburgh, and at the University of Edinburgh, where he graduated M.A. in 1875. In 1892 he was appointed to the professorial chair which he now vacates. In April, 1893, the University of Edinburgh conferred on him the honorary degree of D.D., and in 1895 he received from the Senatus of the University of Aberdeen the honorary degree of L.L.D. Principal Smith has made many valuable contributions to ecclesiastical literature, and the appointment will be a very popular one in Aberdeen. Principal Smith is married to a daughter of Sir George Buchanan, F.R.S., late medical officer to the Local Government Board.

Dingwall Isolation Hospital.

The new Isolation Hospital, erected at Dingwall in connexion with the Ross Memorial Hospital, has been formally opened by Lady Munro of Foulis. The usefulness of this institution has grown steadily since the erection of the first group of buildings in 1873, the extension now opened being rendered necessary by the number of fever cases sent in by the local authorities. Dr. W. Bruce, medical superintendent, introduced Lady Munro, and stated that since its opening, 3000 cases had been treated in the institution, including 140 major surgical cases, and 626 fever cases. The hospital depends entirely on public recognition for its support, but excepting £600 due on account of the balance of the cost of the new isolation building it is free from debt, with an endowment fund of £3000.

Oct. 26th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

University College, Dublin.

The Dublin Commissioners who were appointed by the Irish Universities Act, 1908, held a meeting on Oct. 23rd in the Senate Room of the Royal University Buildings, Dublin, to consider the appointments to the vacant offices in University College, Dublin, and the representatives on the governing body of the College. The names of certain Fellows of the Royal University were selected and recommended to the Joint Committee for appointment, in accordance with the Act, to the various professorships and lectureships in the new University. The list of names of those who have just been recommended to or appointed to professorships in the Medical Faculty is as follows, and in many instances coincides with anticipation: Dr. George Sigerson, zoology; Dr. E. P. McLoughlin, anatomy; Mr. J. S. McArdle, surgery; Dr. B. J. Collingwood, physiology and histology; Dr. E. J. McWeeney, pathology and bacteriology; Dr. J. N. Meenan, hygiene and medical jurisprudence; Dr. Martin Dempsey, materia medica and therapeutics; Sir Christopher Nixon, medicine; Dr. Alfred J. Smith, midwifery and gynæcology; Mr. J. J. Dowling, physics; Mr. J. Bayley Butler, botany; Dr. L. Werner, ophthalmology; Mr. E. L. Sheridan, dental surgery; and Mr. J. L. Potter, dental mechanics. Dr. Collingwood, who has been lecturer on physiology at St. Mary's Hospital, London, is the only imported professor.

The Women's National Health Association of Ireland.

Nearly 100 members of this flourishing association from all parts of the country attended the recent autumn meeting in Dublin at which the Countess of Aberdeen took the presidential chair. Reports of the various sections of the association's work showed, among other details, that babies' clubs, known elsewhere as schools for mothers, have been established at Dublin, Belfast, Cork, and Londonderry, and that in connexion with the clubs classes in home nursing and sick aid have been largely attended by the elder girls. A pasteurised milk depot has been established in Dublin showing most excellent results in saving infant life. Schemes for providing and distributing pure milk from healthy cows have been carried out in various parts of the country, including Belfast, Armagh, Carlow, Killarney, and Cork. Five regular health lecturers have given courses of lectures in all parts of the country, in addition to those provided by local branches and lectures provided by the kindness of

the medical profession. 32 extra district nurses have been appointed in Ireland during the last 18 months through the means of the Women's National Health Association. The Samaritan and Nourishment Funds have done useful work, and the first of the disused Coastguard stations taken over by the association was opened as a health home for preventive cases on August 4th, and since then has received 34 inmates who have all much improved in health. They come from families where they have been exposed to infection from tuberculosis, but are certified free from the disease themselves before admission. In the early part of the year the Tuberculosis Exhibition visited several districts in Ireland, closing with visits to three different quarters in Dublin, where it was visited by enormous crowds of people and where the lectures were so crowded that hundreds had to be turned away every evening. The Tuberculosis Exhibition caravan, designed to meet the need of outlying places too poor to undertake the expenses of a visit from the exhibition, has proved a very successful scheme. It has travelled all round Donegal and is now working in the west of Ireland. A refreshment van selling pasteurised milk and other nourishing and wholesome foods and drinks has been established by the association in the Phœnix Park. Dublin, during the last few weeks especially for the benefit of the football players and has met with a very hearty welcome. About 3,000,000 leaflets, pamphlets, pictures, posters, and literature of all kinds have been published and distributed during the last two years. A series of three volumes entitled "Ireland's Crusade against Tuberculosis," and containing a collection of valuable lectures by leading medical men and other experts on subjects connected with the prevention and treatment of tuberculosis, has been published by Messrs. Maunsel at 1s. each, and copies of the same have been sent free to a large number of persons who are in a position which enables them to promote the anti-tuberculosis campaign. A generous donation for the publication and distribution of these educational volumes and other similar literature has been given by the Vice-President and Council of the Department of Agriculture and Technical Instruction. Siainte, a monthly magazine dealing with health subjects in a popular way, is also published by the association., and has helped to disseminate valuable hygienic information.

The Late Professor Cunningham.

A meeting of friends and former pupils of the late Professor D. J. Cunningham will be held by permission of the Provost in the Medical School, Trinity College, on Nov. 3rd, at 4.30 o'clock, to take steps to establish in the school a memorial of his connexion with Dublin University.

The Health of Belfast.

At a meeting of the public health committee held on Oct. 21st it was reported that the death-rate from all causes was 14.0 per 1000. There is an increase in the notifications of scarlet fever. It was announced that the Belfast corporation is about to promote an improvement and reconstruction scheme under the Housing of the Working Classes (Ireland) Acts, 1890-1908. The main object of the scheme will be to clear certain unhealthy areas and to provide suitable sites for building houses for the working classes. These houses need not necessarily be built by the corporation; in fact, it is probable that the corporation will let the land for building purposes. In these circumstances the Belfast corporation asked the Local Government Board whether it would admit a claim on the part of the corporation to a share in the Irish Housing Fund referred to in Sections 4 and 5 of the Housing of the Working Classes (Ireland) Act of 1908. In reply, the Local Government Board said that it had not had an opportunity of examining in detail the proposals of the corporation, and that, further, it was not in a position to determine whether the scheme contemplated was of such a nature as would entitle the corporation to a contribution from the Irish Housing Fund in accordance with the sections of the Act quoted by the corporation.

Floods in Belfast.

for providing and distributing pure milk from healthy cows have been carried out in various parts of the country, including Belfast, Armagh, Carlow, Killarney, and Cork. Five regular health lecturers have given courses of lectures in all parts of the country, in addition to those provided by local branches and lectures provided by the kindness of

Hall, where a meeting was being held on Saturday night, the people had to leave within half an hour of the opening by a backway, owing to a great part of the buildings being surrounded by water. At the Hippodrome Music Hall the orchestra was swamped and the bandsmen's seats had to be placed on boxes, while the stage door was unapproachable.

A Liberal Workhouse Officer.

At the weekly meeting of the Lisnaskea (county Fermanagh) board of guardians held on Oct. 23rd, the master said the members would be surprised to hear that a female patient drank ten glasses of champagne, three glasses of a medicated wine, and two glasses of brandy in one day. She also took two eggs and three pints of milk on the same day. She died shortly afterwards. The guardians agreed that the medical officer had full power to order whatever he liked for a patient in hospital and the chairman said no pains were spared to save this woman's life. But the amount of stimulants seems very large. Oct. 26th.

(FROM OUR OWN CORRESPONDENT.)

Sanitary Regulations regarding Oysters.

With a view to preventing the sale of unwholesome oysters the Under-Secretary of State for the Navy has ordered a commission appointed under the presidency of the Inspector-General of Fisheries to draw up sanitary regulations regarding oyster culture. The regulations will define the condition in which the beds, pools, and reservoirs used for this purpose must be kept. Owners of oyster beds not complying with the prescribed conditions will only have permission to deal in half-grown oysters; in other words, they will not be allowed to supply consumers. In places where oysters are brought to maturity the licence granted by the Minister of Marine will be withdrawn if the regulations are not observed.

Albuminurio Bronchitis and Pulmonary Catarrh.

At a meeting of the Société Médicale des Hôpitaux held on Oct. 8th M. Bezançon and M. de Jong called attention to the confusion which existed between the conditions known as pulmonary catarrh, albuminuric bronchitis, and even pulmonary cedema. In their opinion, the expectoration in these diseases was of three types—namely, (1) the true sero-albuminous expectoration of pulmonary œdema; (2) hydro-mucous expectoration consisting of water and mucine; and (3) mixed expectoration with pre-dominance of the hydro-mucous type, occasionally containing albumin and leading to confusion with pulmonary cedema. In reality the question was one of bronchial hypersecretion in relation to chronic bronchitis. This bronchial hypersecretion occurring in patients suffering from emphysema associated with cardio-renal disease had perhaps some connexion with urinary elimination. In a patient whose case was followed for a year M. Bezançon and M. de Jong were able to observe a complete parallelism between the quantity of hydro-mucous expectoration and the quantity Under a chlorine-free dietary the expectoration diminished but it increased again when a diet containing chlorides was tried, and at the same time there was free elimination of a chloride in the sputum. Under the influence of digitalis the urine and the sputum increased. When theobromine was given there was an increase of the expectoration only, this being accompanied by cough and dyspnosa, which caused so much pain by irritation of the bronchial glands that the drug had to be stopped.

Etiology and Treatment of Vertical Displacement of the Stomach.

M. Gayet has had an opportunity of observing very marked vertical displacement occurring in a man, aged 50 years, who had for a long time suffered from gastric pain, and this case formed the subject of a paper read by M. Gayet at the twenty-second French Congress of Surgery held at Paris from Oct. 4th to 9th. The pylorus descended to the pubes on the left of the abdomen. The patient, who was the subject of tetany and delusions of inanition, vomited continually and was very emaciated. A complicated operation

was performed, consisting in transmesocolic gastro-enterostomy, completed by jejuno-jejunostomy. After gastroplication, in which the stomach was folded and kept in position by a series (surjet) of silk stitches, its anterior surface was sutured to the abdominal wall in such a way as to restore the organ to its normal position (gastropexy). patient made an uneventful recovery; when seen eight months afterwards it was found that he had become fat, had gained 17 kilogrammes in weight, and digested his food quite well. In the course of the operation it was noticed that the thorax was narrowed in a wasp-like shape, that the liver was small and in the middle line, and that the normal hepatic space was occupied by a portion of the transverse colon. From all this it might be concluded that the wearing of corsets, so often said to be the cause of downward displacement of the viscera, was not always to blame, and that congenital defects had much to do with the pathogenesis of the condition. The treatment was unavoidably complicated, with a special necessity for attention to the sutures in the upper part of the abdomen.

International Congress for the Repression of Fraud.

The Second International Congress for the Repression of Fraud was held in Paris from Oct. 17th to 24th. The first Congress, an outcome of the Universal Society of the White Cross, was organised in Geneva in 1907 and was held in that city in September, 1908. Its object was to promote international action for the prevention of fraud in connexion with food and drugs, and in the realisation of this ambitious programme to bring together manufacturers, merchants, producers, and men of science. Its work commenced with an attempt to define products which were commercially pure. This first Congress received from all countries a welcome so hearty that 21 Governments replied to the invitation of the White Cross, and about 600 members met at Geneva. During this Congress there was only time to define commercial purity as regards alimentary substances, and the examination of the processes requisite for the preparation of food was adjourned to the following Congress which has now closed. The general opening meeting took place in the large amphitheâtre des travaux pratiques of the Faculty of Medicine under the presidency of the Minister of Agriculture, who in a speech which was much applauded expressed an earnest hope that the Paris Congress would worthily continue the work which had been begun in Switzerland. He dwelt on the necessity for conscientious producers and merchants coming to an understanding with persons possessed of technical knowledge for the purpose of defining commercial purity as regards alimentary substances and of drawing up a list of the legitimate processes necessary for their further preparation. In the next place commercial requirements had to be adjusted to the claims of public health. In conclusion, the Minister reminded his audience that it was necessary to appeal to legislators who would complete the work of the Congress by making its conclusions the basis of international arrangements. M. Vuille, President of the Universal Society of the White Cross, then thanked the members of the French Government and the Presidents of the Municipal Council of Paris, and the General Council of the Seine, who had taken the Congress under their patronage. In the next place he gave an account of the work undertaken by the White Cross from the closing of the last Congress up to the present time. M. Bordas, President of the Second Congress, explained the details of the official programmei.e., the examination of the processes necessary in the preparation of alimentary substances in a state of commercial purity and the definition of the primary materials of pharmaceutical and chemical products. The Paris Congress would therefore do what it had been necessary to leave undone at Geneva, and would undertake the drawing up of a list of legitimate operations for the preparation of food. For instance, as a definition of pure wine, it was not enough to say that it was the product of fermented grape juice, but the various processes employed by the producers before delivering the fermented grape juice to the consumers must be enumerated. The French Section of the White Cross of Geneva asked all the mercantile and manufacturing associations to supply it with definitions in respect of each of the alimentary substances prepared or manufactured in France, and after a very careful examination of these documents a series of resolutions would be drafted and submitted for the approval of the Congress.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Infantile Paralysis.

INFANTILE paralysis has for some time been assuming an epidemic character in certain districts of the Rhenish province and Westphalia, as mentioned in this column on Oct. 2nd, and the disease has now increased so much that the Government has asked Professor Krause, the director of the Medical Clinic of the University of Bonn, to inquire into the matter. Epidemics of the disease have already been observed in Norway, Sweden, New York, and Vienna, while in Germany sporadic cases, sometimes occurring in groups, have happened every year. In his report, which has been published in the Deutsche Medizinische Wochenschrift of Oct. 21st, Professor Krause deals especially with the present epidemic in Westphalia. He states that the first case occurred in the town of Hagen in the beginning of the month of June, from which date the number of patients increased till August, and since that time recent cases were also met with in September and October. Oct. 5th, in the very populous district of Arnsberg, including large manufacturing towns such as Bochum, Dortmund, and Hagen, 436 cases and 66 deaths were registered. The age of the youngest child attacked was 4½ weeks and that of the eldest was 15 years, but the majority of cases occurred in children of 2 years of age and of the female sex. Professor Krause recognised two stages of the disease. The first was that of general symptoms, in which pyrexia, perspiration, and troubles of the gastrointestinal canal were the principal features; diarrhœa was more frequent than constipation, and it was remarkable that at the same time diarrhoea usually attacked other members of the same time different stages at the same time the family. It is impossible in this stage to say whether paralysis will develop or not. The children, however, complained of pains in the vertebral column, the neck, and the limbs. On puncture of the spinal canal the cerebro-spinal fluid was discharged under high pressure (from 135 to 140 millimetres of mercury). It was limpid, alkaline, and showed an albuminous reaction. The second stage was that of paralysis; it began, as a rule, with high fever lasting for one or two days, together with acceleration of the pulse and respiration. The paralysis affected first the muscles of the neck, so that the head was drawn backwards or to one side; then the dorsal or abdominal muscles were implicated, so that both the erect and the sitting position became impossible; and finally one or both arms or legs, and sometimes also one side of the face, were paralysed; once an isolated paralysis of the abducens nerve was observed and paresis of the respiratory muscles was present in severe cases. The sensorium was, as a rule, not affected. The paresis might disappear within a relatively short time—from several days to three weeks, but a paralysis of one or both of the limbs usually persisted; in a number of cases, however, the paralysis completely disappeared. The paralysis was of a completely atonic kind; only once a spastic contraction of the right leg was observed; the tendon reflexes had disappeared, whilst the cutaneous, abdominal, and cremasteric reflexes were present. Sensibility was impaired in only one case in which complete anæsthesia was present for two weeks. Post-mortem examination was made in eight cases, the result being that a relatively slight leptomeningitis with circumscribed dull foci was observed. The most striking alteration was, however, present in the gastro-intestinal canal, which showed hyperæmia and swelling of the mucosa, together with enlargement of the mesenteric glands and of the spleen. With regard to the place of entrance of the virus into the system, Professor Krause was of opinion that it must be the gastro-intestinal canal. The nature of the virus is not yet known and nothing has been ascertained as to the manner in which infection is conveyed; it is probably carried by the food, although a great many suckling infants were among the patients. Fruit was alleged by some to be the cause of the disease, and others attributed it to insect pests, but without any apparent ground in either case. A remarkable incident was that together with the epidemic of paralysis an enormous

said to have occurred but to have subsequently disappeared; the post-mortem examination of this bird showed nothing abnormal. The disease may certainly be communicated from one person to another by healthy carriers of bacilli. In the acute febrile stage isolation of the patients is necessary and also disinfection of their dwellings, as in several instances the disease broke out in a family when they had moved to a house where cases of paralysis had happened. To remove the virus from the gastro-intestinal canal the administration of castor-oil or calomel was advisable and the diet must be regulated. Against the general infection inunction of Credé's ointment containing silver might be tried; sometimes the paresis disappeared after puncture of the spinal canal in the lumbar region. The bacteriological examinations made by Professor Krause, in conjunction with Dr. Meinicke, chief of the Hagen municipal laboratory, had no result. Micro-organisms of various kinds were found in the bowels and the urine, but proved to have nothing to do with the virus. The other organs and the fluids of the body were free from bacteria. Attempts were also made to communicate the disease to animals by the inoculation of pieces of organs or fluids obtained from the patients. Mice, guinea-pigs, chickens, and pigeons remained quite healthy, but rabbits were killed in several instances by the inoculation of brain, spleen, or blood; the death occurred sometimes with cerebral symptoms and after a relatively long period of euphoria.

Prosecution for Misdescription in a Medical Certificate.

A medical man in Berlin has recently brought himself into serious trouble while intending to do a kindness to a patient. He attended a girl who was employed in the State telephone service and became pregnant, but had an ordinary miscarriage. As she had therefore to be off duty for some time it became necessary for her to produce a medical certificate. She implored her medical attendant to conceal her state, as otherwise she would at once lose her appointment, and for this purpose to enter some other cause of illness on the blank form. This he accordingly did, stating that the patient suffered from influenza. By accident the truth became known to the authorities, and the medical man was prosecuted on the charge of having wilfully given a false medical certificate, an offence punishable by imprison-Before the court it was stated that the dement. fendant had been induced to commit this irregularity by his good nature only and not for any financial profit, but he was nevertheless found guilty and sentenced to the minimum punishment of one month's imprisonment. case was discussed in the daily press and it is expected that the Sovereign will exercise his prerogative of mercy. In some newspapers it was argued that the present law should be altered because it does not make any difference as to the motives of the defendant, punishing equally a medical man who acted from generous motives and one who made a trade of giving false certificates for money. Regret has also been expressed that the accused did not come before a jury who would certainly have found a verdict of not guilty, but came before three judges who, according to the strict terms of the law, found that he had committed an illegal action. It is hoped that the Berlin medical chamber will petition the Crown to pardon the culprit who is known as a respectable medical man of good standing.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Typhoid Fever Iraced to Milk-supply.

canal. The nature of the virus is not yet known and nothing has been ascertained as to the manner in which infection is conveyed; it is probably carried by the food, although a great many suckling infants were among the patients. Fruit was alleged by some to be the cause of the disease, and others attributed it to insect pests, but without any apparent ground in either case. A remarkable incident was that together with the epidemic of paralysis an enormous mortality was present among chickens, especially the younger ones. A man reported that two of his chickens had died with paralytic symptoms, in a third one the paralysis was

accidental infection of two large dairy farms as the probable cause of the sudden outbreak. Dr. Schiller adds that unless certain defective sanitary conditions now existing in the district be corrected, a repetition of this accident may be expected, in spite of the fact that the water-supply is of good quality. The official bacteriological analysis of this water made at brief intervals during the last six weeks or more points to nothing that would suggest the water in any way to be faulty. The investigation of the milk-supply showed that households which afterwards suffered from typhoid fever since August 15th had in most cases purchased their milk from the same dairyman. Two cases of typhoid fever are known to have developed at his home. As milk is one of the best vehicles for the conveyance of the infection of typhoid fever, it is reasonable to suspect that the disease in the district in question was due to the use of milk accidentally infected on the premises of the dealer in whose family a case existed. As to the general sanitary condition of the towns in Hungary, the Chief Sanitary Superintendent says that many of the houses have no connexion with the street sewers, their facilities for drainage and disposal of waste being over the surface and into the cesspools located in the back yards. There is also a conspicuous lack of sewage facilities in some parts of Budapest. A number of streets have no sewers under them, particularly in Buda, the ancient part of the capital, and in a very large number of houses located in many instances on streets having sewers the house-drains are not connected with the sewers. With the continuation of condi-tions of this kind it would be surprising if epidemics did not occur from time to time.

The Use of Gelatin as a Hæmostatic.

Dr. Pfeiffer has published his recent clinical experiences in the treatment of hæmorrhage by rectal injections of gelatin. The cases which he has observed were 23 in number, comprising 16 of hamoptysis in pulmonary tuberculosis, 4 of gastric ulcer, and 1 each of epistaxis, pulmonary infarct, and purpura hæmorrhagica. The method was as follows: A solution of 15 grammes of gelatin in 150 cubic centimetres of hot water was allowed to cool to the temperature of the body and then injected under slight pressure as high as possible into the colon. These injections were given from one to three times daily and were usually well retained, no evidences of gelatin being visible in the stools. Even after the bleeding has stopped it is well to continue the enemata once daily for several days. The results in many of the cases were quite remarkable. In some of them the bleeding came on again, when the treatment was stopped too soon, but on its being resumed, the bleeding ceased at once. In a few cases the results were negative and in some the effects were not well marked. This uncertainty was also found when the gelatin was injected subcutaneously. The rectal injections are not, however, attended by unpleasant complications; they are free from the dangers of infection and are quickly and readily applied. These advantages may be considered of sufficient importance to warrant the substitution of the rectal for the subcutaneous method.

Oct. 25th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Plague.

THE plague returns for the week ending Sept. 18th show 2353 deaths, compared with 2096 in the preceding week. The Bombay Presidency reported 693, Madras 185, Bengal 58, the United Provinces 353, the Punjab 68, Burma 42, the Central Provinces 596, Mysore State 169, Central India, 109, and Rajputana 60.

The Health of Bombay City.

As was to be expected, the return of rainy weather, driving the poorer people from the open air into their unwholesome houses to sleep, has checked the promising decline of plague in Bombay. The returns for the week ending Sept. 21st show a total of 12 deaths, as against 9 in the preceding week, and the daily figures show a slight upward tendency. Last year's record for the corresponding week was 26 deaths, and the quinquennial mean 34,

so there is still room for hope that we may achieve what has never happened yet since plague first appeared—a clean sheet in Bombay for a whole week. The deaths from cholera for the same week were 20, another figure which shows an upward trend, although there appear to be fewer imported cases than usual. The total mortality in the city shows a distinct improvement, having gone down to 578 for the week, as against 591 in the previous seven days. The improvement on the five-yearly mean of 640 is considerable, but last year's figure was only 561. The question of safe-guarding the milk supplies of the city is still far from being satisfactorily settled in Bombay. Several wise measures which the executive health officer has pressed upon the corporation are still unadopted, and Dr. J. A. Turner is now trying to solve the problem piecemeal by suggesting the establishment of municipal pure milk depôts, for the benefit of babies, as a beginning.

The Malaria Conference.1

In addition to the officers recently mentioned, the following will attend the Malaria Conference at Simla on Oct. 11th: Surgeon-General F. W. Trevor, Principal Medical Officer of His Majesty's Forces in India; Colonel C. P. Lukis, I.M.S., officiating Director-General, Indian Medical Service; Lieutenant-Colonel J. T. W. Leslie, I.M.S., Sanitary Commissioner with the Government of India; Lieutenant-Colonel D. Semple, R.A.M.C., Director of the Research Institute; Lieutenant-Colonel A. R. Aldridge, R.A.M.C.; Lieutenant-Colonel J. Thornhill, Indian Army, Inspecting Officer of Cantonments; Major S. P. James, I.M.S.; Captain S. R. Christophers, I.M.S.; Major C. Donovan, I.M.S., Professor of Philology, Medical College, Madras; Diwan Bahadur Narayane Murti Pantulu Guru and an administrative officer still to be nominated from Madras; Lieutenant-Colonel T. E. Dyson, I.M.S., Sanitary Commissioner; Mr. Lawrence, Collector of Sukkur; Mr. J. A. Wadia from Bombay; Mr. Maude, Commissioner, Patna; Major Leonard Rogers, I.M.S., and Rai Kissori Lall Goswami Bahadur from Bengal; Mr. Ferard, Commissioner, Allahabad; Major J. Chaytor White, I.M.S., Sanitary Commissioner; and the Hon. Pandit Sunder Lall from the United Provinces.

British Troops and Malaria.

Orders have been issued that British troops now in hill stations are not to move to the plains until Nov. 15th, and where malaria is reported in cantonments the movement is to be delayed until Nov. 30th. The extra time in the hills may be employed in local manœuvres, provided these do not interfere with subsequent divisional manœuvres. The troops should benefit materially by their longer stay in the more bracing climate of the hill stations.

Sept. 24th.

CHINA.

(FROM OUR OWN CORRESPONDENT.)

Journey through Shan-si.

I RETURNED last week from a journey of over 1000 miles by road, river, and rail in Shan-si, an important province in which, up to last year, the largest amount and the best quality of opium were produced. Shan-si opium was prized all over the Empire by smokers as well as for medicinal purposes. As the result of particular inquiries and observations, I am able to say that a determined campaign has been prosecuted by the officials and that the output has not only been very materially reduced but that the people are finding great difficulty in continuing their indulgence in the pipe. Itinerant merchants sell the drug, but under difficulties, and opium smoking is now become a vice that can only be followed out secretly and circumspectly instead of being, as before, a habit that was not regarded among the people as a vice. Some of the wealthier families have laid in a stock of opium that will last them for years, but the enhanced price is now beyond the means of the poorer classes, and there are no new smokers among the younger generation. In Shan-si until recently women smoked freely as well as men. One can still see in the sallow, anemic faces of many men in the towns traces of

¹ We published last week the outline of the recommendations arrived at by the Conference, which reached this country by telegram. (See THE LANCET, Oct. 23rd, p. 1231.)

their years of indulgence. The rough-and-ready cure of stoppage of supply was referred to feelingly by several natives to whom I spoke. Thus, as far as Shan-si is concerned, the predictions of those who had studied the question among the Chinese, and knew how deep was the narcotic hold the drug had taken of the people, appear to be falsified. But any relaxations on the part of the officials for some years to come will find the people ready to relapse, as they are non-smokers now only by force of circumstances. Anti-opium pills are in extensive use, and there is good reason to believe they are of the nature I have indicated in previous notes. The use the nature I have indicated in previous notes. of morphia in hypodermic syringes seems to be mainly confined to the coast ports, and it is almost unknown in the country towns and villages. Throughout the whole journey I did not remark a single case of alcoholic intoxication. In all this vast tract of country through which I travelled, with the exception of one town, Taiyuanfu, I did not meet any Europeans, missionary or otherwise, and there is here a wide field for foreign medical work. There were many demands for treatment, which I was rarely able to give. Rheumatism is not uncommon among the older people; there were many cases of dyspeosia, mainly due to intestinal parasites and the bolting of food; eczema and "itch" are common in the towns, and tuberculosis and trachoma are widespread. In every village there were many cases of this last disease, for which the native pharmacopœia has no antiseptic check. leaves in its trail blindness, entropion, and corneal opacities. In some of the larger towns, such as Kuei-hua-cheng, where there is a rich mercantile community in a population of over 80,000, a remunerative practice awaits the first foreign doctor, a knowledge of the dialect being, of course, a necessity. Foot-binding is de rigueur among Shan-si women and the feet are bound smaller than in other provinces. In most cases the binding is so tight that the women appear to be walking on amputated stumps. Harvesting was in progress and in every field could be seen the women hard at work reaping on their knees owing to the difficulty of supporting their body-weight for any length of time on their diminutive feet.

An International Medion-legal Case.

It is only a matter of a few years since the Chinese found out the powers of trade boycott, and it has in their hands become at times a weapon which has caused no little injury to the trade of the country against which it is enforced. Four years ago America was involved. During last year Japan suffered, and now England is in a fair way to become the chosen enemy-this time by the people of Kinkiang, who are banding themselves together to have nothing to do with British ships and commerce till they get "satisfaction," or, in other words, the heavy punishment of a consular constable and compensation for the so-called "murder" of a Chinese native. The circumstances were these. The constable was said to have administered a blow with his cane to a coolie who fell down and at once became very ill. No one actually saw the blow being given, but the man was close beside the constable (an Englishman) when he dropped on his knees with a groan. The constable went forward and on turning the man's face round found him ashy pale and had him at once removed to the British Consulate, where he was seen by Dr. Lambert, a Canadian, who pronounced his condition as very serious and gave him a stimulant and strychnine injection hypodermically. At the man's own request an attempt was made to remove him to his house but he died on the way. Dr. Lambert concluded that the man was suffering from internal hæmorrhage which might have resulted from other causes than a blow. He examined the body and found no signs of any blow. In his opinion death was due to internal hæmorrhage and to that only. Dr. Lambert said in his evidence that he had some conversation with the constable Mears which left a general impression that there had been a poke by Mears, but he could not make any positive assertion. As the judge in his summing up said: "It seems highly improbable that had Mears said he poked Yü (the dead man) Dr. Lambert would not have had much more than a general impression-such a statement could not but have made a definite and lasting impression on his mind. Dr. Lambert could not say that Mears had struck Yü and he could not say that death was due to a blow." The body was allowed to lie unburied on the road at the spot where death occurred for 11 days with only a slight covering of sand before a necropsy was undertaken by an American,

Dr. E. H. Hart, a medical missionary from a neighbouring port, who was called in by the Taotai (prefect) of Kinkiang as a result of an agitation amongst the Chinese. This necropsy was performed at 4 A.M. in the dark on the road by lamplight. In a temperature averaging 70° F. and a humid atmosphere it may be judged that the body was then in a state of general putrefaction. Dr. Hart stated in his evidence that the liver, spleen, and kidneys were normal in shape and size, but that he was not allowed to remove them, nor did he make sections into them and was unable for want of microscopical examination to say there had been no previous disease. On opening the abdomen there was an escape of gas and blood, and, in addition to the blood he found lying free in the abdominal cavity, there was also blood inside the intestines. The peritoneal surface of the intestines was covered with numerous petechiæ of extravasated blood. He found a mark on the left flank of the abdomen which was of a "purplish-black" colour, and though he did not incise this "mark" he stated his conviction that it was a contusion caused by a blow, and he eventually pronounced death as being due to hæmorrhage in the abdominal cavity caused by a blow without in any way indicating the source of that internal hæmorrhage. When asked by the Consul what were the signs of decomposition he said that "the first signs are the body becoming black." It is not in accordance with medico-legal experience that a contusion should remain "purplish-black" or, seeing that no marks of violence could be detected during life, that the discolouration in the peeling skin of an 11 days old body could be so well differentiated, especially by lamplight, as to enable anyone to attribute hæmorrhage to a blow. Dr. Hart admitted that he could not swear to the discolouration being the result of a blow and not simply due to decomposition. For lack of any expert cross-examination his evidence was allowed to go forward without criticism, and, needless to say, it gave the Chinese a handle to their cause which they have not been slow to take advantage of, with the result that, although the defendant was discharged, the British authorities have been placed in a difficult position. Meanwhile, the wheels of the boycott machinery having been set in motion, and local ill-feeling against everything British having been aroused, it will require tact and work on the part of both British and Chinese authorities to show the people that it is absurd for them to describe such a case as one of murder. Foreign medical evidence, however loosely given, is taken as being absolutely in accordance with fact; it would therefore have been better to have avoided making the deduction that death was the result of a blow from such a superficial necropsy. When the doctor who made the necropsy pronounced all the organs as healthy it would have made his evidence of more import if he had given due weight to the presence of petechiæ on the bowel surface—a sign indicative of some morbid hæmorrhagic condition during life. It would also have spared him the animadversions of the judge, who referred to it as "a most extraordinary autopsy which was not only useless but improper. It was also illegal." Peking, Sept. 29th.

University of Liverpool.—At a meeting of the Faculty of Medicine held on Oct. 22nd the Dean announced the entries for the winter session as follows:-Medical School: New entries for degree courses, 23; new entries for diploma courses, 8; total number of undergraduates registered, 132; new entries for the Diploma of Tropical Medicine, 19; new entries for the Diploma of Public Health, 13. Dental School: New entries for degrees and diplomas, 14; total number of dental students registered, 42.

THE DEWSBURY INFIRMARY.—On Oct. 19th Sir T. Clifford Allbutt visited his birth-place, Dewsbury, to open a new nursing home and operating theatre for the Dewsbury He delivered a retrospective address concerning Infirmary his medical and hospital experiences in Leeds and the neighbourhood, and made an appreciative reference to the progress of modern nursing. He also described how the improvement of the sanitary conditions of the country by preventive medicine had decreased greatly the malignancy as well as the frequency of infective disease. Sir Clifford Allbutt was

Obituary.

CESARE LOMBROSO.

ITALY, it has been said, is the only country in Europe besides Great Britain which offers a career to the Jewish race. Certainly she stands alone among her continental sisters in affording counterparts in politics to D'Israeli and Goschen; in law (international and civil) to Herschell and Jessel; in public health to John Simon. In this last-named field she is now mourning the loss of a conspicuous and, in many respects, most salutary worker, Cesare Lombroso, whose life, strenuous and public-spirited, was spent in applying nature study to the physical, mental, and social rehabilitation of Italians, and, indirectly, of the outlying Latin civilisation.

Born in Verona on Jan. 10th, 1836, he was the second son of Aronne Lombroso and Zefira Levi, from both of whom, particularly the mother, he inherited a bright intelligence and an instinctive devotion to the good of his fellow-man. As precocious as John Stuart Mill in linguistic aptitude, he had a working knowledge of Greek and Latin when most boys are learning the grammar of their native tongue, and when in his fifth year he would read aloud to his mother one of "Plutarch's Lives," and then at her bidding would give orally a detailed résumé of the "Life" just read. Sallust, Livy, and Tacitus were all, in his eleventh year, familiar to him in the original, and Dante, mainly through his father's encouragement and aid, he knew well-nigh by heart. In 1850 he was pursuing philological study under Paolo Marzolo, extending its application, thanks to that great scholar and teacher, to "comparative religion" and "comparative civilisation"; but, again at Marzolo's instance, he turned his attention to nature-study and found in it a yet more congenial outlet for his mental powers. He matriculated as a student of medicine in the University of Pavia in 1853 and continued at the classes till the outbreak of the War of Independence in 1859, by which time he had graduated with special qualifications in surgical pathology. On the army medical staff and in the field he acquitted himself with equal skill and courage, and shortly after the revindication of Lombardy to Italian unity he made accurate studies in mental disease, so utilising his opportunities in the lunatic asylums, urban and provincial, that his appointment to the chair of Psychiatry in the Scuola Pavese followed as a matter of course. In 1862, when Darwin's "Origin of Species," published three years before, had taken a hold on the Italian mind which it has never lost, there were few more convinced and enthusiastic students than young Lombroso. By this time he had applied experimental induction to the study and classification of insanity and its types, and from the observations then made and registered he proceeded to connect mental processes and developments with physical organisation, thus laying the first lines of what in later years became the science of which he was virtually the founder, that of "criminal anthropology." While still a teacher in the University of Pavia he became interested in that terrible scourge of rural Italy, "pellagra," and starting from the admirable work of Ballardini he traced it to a specific poison originating in the "corrupted maize" which enters so largely into the diet of the agricultural labourer. Following up his researches he noted the forms of mental disease supervening in the sufferers from pellagra and how these assume various characteristics in keeping with individual organisation. These findings were indeed side-lights on the theory he was gradually, and amid much opposition, both at Pavia and Milan, evolving as to the correlation and interdependence of somatic and mental pathology, afterwards to culminate in his "Uomo Delinquente" or "Oriminal-Né." "Crime," according to him, is the reflex, in the sociological field, of the organic anomalies of the delinquent-anomalies deep-seated, which, in their essential part, must be sought in the nerve centres, and in their accessory part in the other apparatus of the body, particularly in the osseous system. In as far as they are traceable to the nerve centres they produce psychical alterations quite characteristic and betray their degenerative nature in two ways: (1) in as far as they are the reproduction of an atavic character, corresponding to anterior stages of development of the human 'Psyche,' and reveal an

'arrest of development' which places the individual on a lower plane than his fellows; (2) in as far as they are the reproduction of an epileptic character and assimilate the 'delinquente' to a 'neuropathic'—epilepsy being one of the graver, more pronounced degeneracies known as 'neuropathiae.'" Such is the theory, the practical result of which is to recognise in the individual the "accessory anomalies" (of the osseous system, inter alia) as the organic cause of his "delinquency," and, further, to combat the tendency in the organic substratum of the race. Criminology, so conceived and applied, transfers crime from the sphere of traditional jurisprudence to that of anthropological and psychiatric

This is not the place to examine what elements-more or less—of truth the theory possesses, suffice it to say that the book in which it was set forth appeared in 1876 and at once commanded attention and provoked controversy often keen, sometimes embittered. That it was not without a considerable measure of acceptance may be inferred from the fact that "Criminal Anthropology" is so far recognised as a science as to number many votaries whose periodical congresses on an international scale, and held in the chief capitals of Europe, are now a standing feature in contemporary life, medical, forensic, and sociological. On the same lines as the "Uomo Delinquente" followed his treatises on the "Uomo di Genio" (written in conjunction with his sonin-law, the brilliant historian of ancient Rome, Guglielmo Ferrero), and his studies on "Delitto Politico," on the "Donna Delinquente," and, more especially in the psychological field, on "Mediumismo." Of these it is unnecessary to give an appreciation, standing or falling, as they do, with the initial work, "L'Uomo Delinquente." Called to the chair of Criminal Anthropology in Turina chair he may be said to have founded—he sent forth year by year relays of enthusiastic votaries of the science whose intervention at the International Congresses kept his theory in evidence, if not always in acceptance, before the delegates of all the other European schools. Among these Congresses the most animated and memorable was that held at Geneva in the August of 1894, in which Lombroso himself and his intrepid young henchman Enrico Ferri were the protagonists. He was, indeed, more effective in debate than in academic exposition in the professorial chair, when his digressions and parenthetical 'vindications" obscured the theme in hand to all but the initiated few.

Apart from his official duties and his provocative theories, no man was more beloved as a citizen or more respected as a publicist—his transparent honesty in address as in motive winning the sympathies of all who came in contact with him, inspired as he was with the purest philanthropy and belief in the progress of man. For years past his physique had begun to show signs of senile degeneration; cardiac trouble supervened, and though the end came suddenly at 5 A.M. on Oct. 19th, those near and dear to him were not unprepared for it. On the night before he had been particularly vivacious at dinner, discussing with his family and guests the "tragedy of Montjuich," the crisis in Spain, the Tsar's coming to Italy, and all the exciting topics of the hour. At 11 P.M. the party broke up and he retired to rest; but at 2 A.M. his wife became aware that he was suffering from severe cardiac spasm. Soon all the inmates of the house were at his bedside-his gifted daughters Gina and Paola, his son Ugo (assistant to Dr. Luciani, professor of physiology in the Roman School), and later, his two sons-in-law, Guglielmo Ferrero and Mario Carrara (professor of legal medicine in Turin). But he never regained consciousness and "entered into rest" three hours after the seizure. All Italy has joined in lamenting his loss—the leading journals appearing in black borders and commenting on his life and work, with singular unanimity extolling the tenor of the one and the value, theoretical and even practical, of the other. A public funeral, the largest and most conspicuously representative witnessed of late years in Turin, attested on Oct. 20th the esteem and affection in which he was held in the city and province, and among the oraisons functors customary on such occasions in Latin countries, those of Luigi Pagliani, Professor of Hygiene; of Teofilo Rossi, the Syndic; of Enrico Ferri, Professor of Criminology in the Roman School; and of his son-in-law, Guglielmo Ferrero,

man of letters and historian, went home to the hearts of the audience for their pathos and power.

As we write we are informed that a book on which the last years of his life were employed will soon be published at Turin, entitled "Ricerche sui Fenomeni Ipnotici e Spiritici" (Researches on the Phenomena of Hypnotism and Spiritism). A handsome octavo of over 300 pages and with 57 plates illustrative of the text, it forms the latest enrichment of a literature to which nearly every civilised country has contributed, the English-speaking world being represented by Crookes, James, Hislop, Lodge, and Wallace, whose work is criticised or supplemented in its pages.

WILLIAM CLIBBORN, B.A., M.D. DUB., L.R.C.S. IREL.

Dr. William Clibborn, who died suddenly from cardiac syncope on Oct. 13th at Earl's Court, was the son of John Clibborn of Dublin. He was educated at Stackpoole's College, Kingstown, and graduated M.D. of Trinity College, Dublin, in 1878, and also took the Diploma of the Royal College of Surgeons in Ireland in 1875. He held many public medical and hospital appointments in Dublin and Birmingham, and finally settled in Bridport, where he practised for 20 years and gained many friends and took a prominent part in local affairs. He held the posts of medical officer of health, Admiralty surgeon, and other appointments. He was one of the pioneers in the foundation of the Medical Sickness and Assurance Society, which has enjoyed such a great success. Five years ago Dr. Clibborn retired from active practice, finding the fatigue and exertion inseparable from a large and widely scattered country practice too great a strain, and since then he has been travelling abroad for the benefit of his health. His genial manner, good nature, and thoughtfulness for others endeared him to all who knew him. He leaves a widow and many friends by whom he will long be remembered.

DEATHS OF EMINENT FOREIGN MEDICAL MEN. - The death of the following eminent foreign medical man is announced: Dr. Xenophon Ch. Scott, Professor of Ophthalmology in the Western Reserve University, Cleveland.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated :-

in the subjects indicated:

Surgery.—N. B. Benjafield (Sections I. and II.), University College Hospital; H. S. Brown (Section II.), Birmingham; M. Graves (Section I.), London Hospital; A. W. Hansell (Sections I. and II.), Leeds; J. A. Jones (Section I.), Manchester; E. Newhouse (Sections I. and II.), Leeds; S. K. Poole (Section II.), Guy's Hospital; S. H. Seott (Section II.), London Hospital; and G. Tate (Sections I. and II.), King's College Hospital.

Medicine.—H. E. Battle (Sections I. and II.), Leeds and University College Hospital; H. S. Brown (Section II.), Birmingham; B. Robertshaw (Section II.), Manchester; S. H. Scott (Section II.), London Hospital; H. Stanger (Section I.), Leeds; and J. W. Williams (Section II.), Guy's Hospital.

Forensic Medicine.—H. E. Battle, Leeds and University College Hospital; E. G. Brisco-Owen, Cartiff and Royal Free Hospital; H. S. Brown, Birmingham; F. F. L. How, Middlesex Hospital; B. Robertshaw, Manchester; and H. Stanger, Leeds.

Midwifery.—C. S. Foster, Middlesex Hospital; A. W. Hansell, Leeds; D. M. Hunt, London Hospital; and A. H. Rich, University College Hospital.

The Diploma of the Society was granted to the following candidates.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—N. B. Benjafield, H. S. Brown, B. Robertshaw, S. H. Scott, and G. Tate.

TRINITY COLLEGE, DUBLIN.—At examinations held recently the following candidates were successful:-

INTERMEDIATE MEDICAL EXAMINATION. Part I.—William O. W. Ball, William P. Croker, Walter Crane, Jane F. Colquboun, Maurice Horan, Marjory Chapman, Charles F. Judd, James N. G. Nolan, and Francis V. Agnew.

PRELIMINARY SCIENTIFIC EXAMINATION.

Physics and Chemistry.—Theodore Allen, Robert A. Flood, Reginald H. Jones, William Foot, Joseph Harvey, John W. C. Stubbs, John A. Mac Mahon, Rupert C. Lowe, Henry C. D. Miller, Hawtrey W. Browne, Kathleen D. Wallace, and Eleanor Taylor. Botany and Zoology.—Amos G. Varian, John T. M'Cullagh, George S. M'Conkey, Joseph Harvey, Ernest Bantry White, Hilda M. B. Marsh, Frederick R. Sayers, Michael J. Ryan, Bertram Sheridan, and Frederick A. Sparling.

PREVIOUS DENTAL EXAMINATION. Anatomy and Institutes of Medicine. - Henry Kirk.

FOREIGN UNIVERSITY INTELLIGENCE. Buenos Ayres: Dr. Faustino J. Trongé has been appointed Assistant Professor of Clinical Midwifery and Dr. Rudolfo Erauzquin Assistant Professor of Odontology. - Cologno (Academy of Practical Medicine): Dr. Kayser, docent of Surgery, has been granted the title of Professor. - Padua: Dr. Luigi Messedagalia has been recognised as privat-docent of Medicine. - l'alermo: Dr. Giovanni de Gaetani has been recognised as privat-docent of Internal Pathology, and Dr. Antonio Coletti as privat-docent of External Pathology.—
1 Prague (German University): Dr. Alexander Marguliés,
privat-docent of Psychiatry, has been granted the title of Extraordinary Professor.

Central London Throat and Ear Hospital..-Mr. Charles A. Ballance, M.V.O., will deliver an address on "The Lesson to be Learnt in London from the History of the Mastoid Operation" at the Central London Throat and Ear Hospital, Gray's Inn-road, on Monday, Nov. 8th, at 4.30 P.M.

LITERARY INTELLIGENCE.—"A Bibliography of Trypanosomiasis," embracing original papers published prior to April, 1909, and references to works and papers on Tsetseflies, especially Glossina Palpalis (Rob.-Desv.) and on Sleeping Sickness, has been compiled by C. A. Thimm, of the Sleeping Sickness Bureau, and is now in the press. The work will be issued under the direction of the honorary managing committee in a few weeks.

ORAL SEPSIS AND TETANUS.—At an inquest on the body of a woman, who died from tetanus last week at Southwark, it was given in medical evidence that the teeth were in a very bad state and the septic condition of the mouth might have been responsible for the entrance of the infection. There was a slight wound on the toe, but this had occurred within three days of the onset of symptoms and was therefore probably not responsible for the disease. Dr. F. J. Waldo, the coroner, took the occasion to warn the public on the dangers of neglecting the proper care of the teeth.

HEALTH OF CYPRUS. — Sir Charles King-Harman, K.C.M.G., High Commissioner of Cyprus, in his report to the Secretary of State for the Colonies for 1908-09. remarks that the public health of the island was not so good as in previous years owing to an outbreak of epidemic cerebro-spinal meningitis of an extensive and violent character, which occurred, almost simultaneously, in nearly every district. The number of cases reported was 558, and of these 280, or a little over 50 per cent., terminated fatally. The disease as a rule attacked the poorest class of persons living in damp insanitary dwellings, while those living in more comfortable and cleanly circumstances were, generally, immune. Malarial fevers also were more prevalent than in ordinary years, and large quantities of quinine were imported and distributed for their treatment. The deathrate from this cause was not heavy. Sporadic cases of typhoid fever and a considerable number of cases of influenza detracted also from the general good health of the island. The rural medical service was further extended during the year by the appointment of two additional medical officers. This branch of the service does good work among the villages and is greatly appreciated by the people. The number of inmates of the leper farm at the close of the year was 98, one more than at the end of the preceding year. The general health of the inmates was good; the number of deaths was four. The children of these unfortunate people are cared for and brought up in a separate institution. They number 11, of ages from 2 to 13 years, and up to the present time no sign of leprosy has developed among them. With the exception of a grave crisis in the wine industry, the reports from the several districts of the island indicate a continuance of the prosperity of the people. The standard of living continues to improve and the requirements of the villagers become less simple and more expensive to satisfy. This is abundantly manifested in the improved style and furnishing of their dwellings; in the increasing demand for, and readiness to purchase, land for cultivation; in the higher prices demanded for their produce; in the restoring and re-building of their churches and schools. The Commissioner adds: "There are those who maintain that the British occupation has done nothing for their country and who

remain wilfully blind to the progress which the island is making, but to any impartial observer, to anyone who was acquainted with the state of affairs which existed 30 years ago, that progress is as clear as the sun in the firmament."

THE Edinburgh University Club in London will hold its next dinner on Friday, Nov. 12th, when the chair will be taken by Mr. J. D. Malcolm.

A considerable extension of the accommodation of the Royal Eye and Ear Hospital at Bradford is contemplated, for which some £10,000 are required.

A COOKERY EXHIBITION. — The Twentieth Universal Cookery and Food Exhibition will be held at the Royal Horticultural Hall, Vincent-square, Westminster, from Nov. 2nd to 6th inclusive.

Donations and Bequests.—A sum of £1000 has been voted by the Governor and Court of the Bank of England to the special fund in aid of St. Bartholomew's Hospital. An anonymous donor has also contributed £250.

THE EVELINA HOSPITAL.—The committee of the Evelina Hospital for Children regrets to announce that, owing to ill-health, Mr. Charles Wightman has resigned the chairmanship, a position which he has held for some years with considerable advantage to the institution. Mr. Donald Malcolm Scott has been chosen as his successor in the chair.

PRESENTATION TO A MEDICAL PRACTITIONER. On Oct. 19th at Rugby Mr. T. Johnston, M.R.C.S. Eng., was presented with a marble clock as a mark of respect and esteem by the members of the Ancient Order of Druids, of which he is a Past Arch, on the occasion of his leaving Rugby to take up a practice in Hove.

WestRIDING MEDICAL CHARITABLE SOCIETY.—Comment has been made in these columns on more than one occasion on the excellent work done by this association. The annual meeting, which is held in different centres in the West Riding, took place at Harrogate during the month of September and was well attended. The thought that was uppermost in the minds of all who were present was the sad one that by the hand of death the society had been deprived of its most distinguished, its most enthusiastic, and its most judicious head in the person of Mr. C. G. Wheelhouse. His connexion with the society is briefly summarised in the opening paragraphs of the annual report, which was read at the meeting, and which runs as follows :-

follows:—
"We meet to-day under the shadow of a great bereavement. For the second time in its history our society has to mourn the loss of a presiding spirit." Such were the words used by Mr. Wheelhouse in reference to the death of the late Dr. Chadwick when writing the annual report in 1837. Now, 22 years later, a third epoch is brought to a close by the death of him whose words have been quoted.

Mr. Wheelhouse's father was one of the stewards appointed at the first annual meeting of the society and his partner, Mr. Garlick, was its first secretary. It was not unnatural, therefore, that Mr. Wheelhouse himself should take a deep interest in the charity, an interest which was ripened by the warmth of his kindly nature into an affection and love which remained unaltered and undiminished until the day of his death.

love which remained unaitered and undiffinished until the day of ms death.

Mr. Wheelhouse joined the society in 1853, in which year 15 grants, amounting to £291, were voted. In 1874 he was appointed joint secretary with Dr. Chadwick, and in the following year was asked to undertake the duties of treasurer in addition; his first duty in the latter office was to hand to stewards the sum of £515 for the payment of 19 grants. Last year, after the annual meeting, from which, to his great grief, falling health kept him away, he issued cheques for £1680—the amount of your grants to 49 applicants. It was always a joy to him to contemplate the increasing benefits the charity was able to bestow and to feel it was in some measure due to his careful administration that the means were forthcoming wherewith it was possible to meet these growing demands. The society is also indebted to its late treasurer for his labour in compiling "The story of its origin and early years," which was published in 1901.

His cheery presence, his power of speech, and his whole-hearted devotion to the interests of the society will always be a pleasant memory and a bright example to those who were associated with him.

For many years Mr. Wheelhouse had the valuable assist-

For many years Mr. Wheelhouse had the valuable assistance of Mr. Herbert Rowe, who under his guidance has mastered all the details of the management of the association and who is manifestly imbued with the same spirit of whole-hearted enthusiasm for its welfare. It was natural therefore that he should have been appointed Mr. Wheelhouse's successor and the unanimity and cordiality with which this was done were a tribute to the excellence of his which this was done were a tribute to the excellence of his long services. Grants were made at the annual meeting to Andrew Fullerton, Mr. A. Pearce Gould, Dr. Hector 47 applicants amounting to £1625, and the total amount Mackenzie, Mr. A. W. Mayo Robson, Dr. J. J. Perkins,

made in grants since the commencement of the association is thus brought up to the large sum of £47,920 10s.

MEMORIAL TO PROFESSOR LIONEL S. BEALE. On Oct. 20th a bronze memorial tablet was unveiled in the chapel of King's College Hospital to the late Professor Lionel S. Beale. The tablet was designed, worked, and erected by his son, Mr. Peyton T. B. Beale, F.R C.S., surgeon to the hospital and the present Dean of the Medical School. The inscription sets out very simply Dr. Beale's long connexion with the hospital, exactly 50 years, as physician and consulting physician. Among those who were present at the ceremony, which was a private one, were, in addition to the members of Mr. Beale's family, the Hon. W. F. D. Smith, M.P. (chairman of the hospital), Colonel C. F. Fellows, Mr. L. W. Byrne, Dr. Nestor Tirard (senior physician of the hospital), Dr. Urban Pritchard, Dr. N. Dalton, Dr. G. B. Flux, and members of the nursing staff, past and present. After a very short service by the chaplain, the Part T. B. I. Parker the part T. the Rev. T. B. J. Parker, the unveiling ceremony was performed by Dr. Tirard, who delivered the following address:-

In unveiling this memorial tablet I have asked permission to say some few words—and they are few, not because there is not much that might be said, but because it is felt that it would have been his desire. The tablet is a simple record of his name and the dates during which he worked within these walls. That his work was esteemed is shown from these dates, since they indicate service, continued by request, beyond the normal span. Of the nature of his work, of his cheery service in the wards, of the practical nature of his teaching, of his care for the interests of the school and for the nursing staff, it is not the time for me to speak. I like to cherish three bright memories: in 1872-73 his eagerness in welcoming junior students and others and showing them his microscopic treasures; in 1833 his ready help, when he gave me the results of his experience when I was undertaking new and difficult work; and then, the brightest of all, when at Weybridge amongst his flowers he showed that marvels could be effected by patient skill, not forcing, but encouraging. Patient and cheerful, fearless when defending his firm beliefs, he was, to those who had the privilege of working with him, a perpetual example. The tablet does no more than to say that he worked here for many years. Though it will serve to keep this fact before those who come after us, we who knew him well still feel the influence of his life, still benefit by his experience, and to us he still lives. In unveiling this memorial tablet I have asked permission to say some us he still lives.

In these days, when the subject of pathology is of such moment, it is fitting that a memorial should be erected at the hospital where he worked so long to this pioneer among pathologists, whose work, especially in the application of microscopic methods to the diagnosis of diseases, was and is of the first importance.

STANDARDISATION OF BREAD.—The Bread and Food Reform League has issued a document concerning the standardisation of bread, stating that whole meal, which should be ground to a uniform fineness, contains about two and a half times more of the mineral substances which form bones and teeth, and nourish the brain, nerves, and tissues, than white flour, and that it also contains four times more iron, a considerable portion being found in the germ in a readily digestible condition. The League urges that household bread should retain the germ, which has singular richness in oil, in nitrogenous matter, and in phosphoric acid, and also the semolina, a portion of the wheat, very rich in flesh and bone-forming materials and in fat, but with little fibre. The semolina was formerly retained in household flour, but millers now separate a large percentage of it, and use a considerable proportion for their expensive patent flours, to the detriment of ordinary household flour. The Bread and Food Reform League advocates that the bread of the people should contain this semolina and has obtained guarantees that it is retained in the old-fashioned household bread now used, on the league's recommendation, at Christ's Hospital (Blue Coat School) and at dinners provided for children at London County Council schools by the Alexandra Trust. The league further states that "it is very desirable that a standard should be fixed for what is sold as bread. This has been established for milk, and the standardisation of bread is even more important, as bread and flour form about two-fifths of the weight of food consumed by the working classes, and constitute almost the sole diet of many poor children. A supply of nourishing A supply of nourishing the signatories to this statement are Sir J. Crichton-Browne, Sir John Brors Sir J. bread is therefore of vital national importance." Browne, Sir John Byers, Sir J. Halliday Croom, Sir

Professor Smith, Dr. H. Hammond Smith, Dr. David Walsh, Dr. C. Theodore Williams, Dr. B. C. A. Windle, Professor G. Sims Woodhead, and other medical men. Further information can be obtained from the honorary secretary, Bread and Food Reform League, Miss May Yates, 5, Clement's-inn, Strand, London, W.C.

THE WINDSOR AND DISTRICT MEDICAL SOCIETY. —The annual general meeting of this society, which was held in the board-room of King Edward VII. Hospital, Windsor, on Oct. 14th, under the chairmanship of the President, Dr. Francis H. Hawkins of Reading, was a particularly interesting function. After the adoption of the honorary treasurer's report the President delivered his address, which, in addition to other topics, recounted various matters of interest in the history of the society from its foundation to the culminating point in its career-namely, the inauguration of the handsome library within the walls of the hospital. At the close of the meeting an adjournment took place to this new library, which was formally declared open by Sir Richard Douglas Powell, President of the Royal College of Physicians of London, who at the same time unveiled a portrait of Mr. W. B. Holderness, J.P., who had presided over the society for the first seven years of its existence. Sir Richard Douglas Powell presented the library with a copy of the handsomely bound facsimile reproduction of the diploma granted to William Harvey by the University of Padua in the year 1606, which was published last year by his College. He also spoke at some length on the value of libraries to societies of medical men and their value in forming a bond of union between provincial hospitals and the neighbouring practitioners. Mr. W. J. Handfield Haslett (Sunbury) in an eloquent speech moved a formal vote of thanks to Sir R. Douglas Powell for his kind attendance—a resolution which was seconded by Mr. Holderness in a speech in which he also thanked the society for the honour which it had conferred upon him in placing his portrait in the library. Mr. P. J. de Paravicini, chairman of the hospital committee, also spoke on behalf of the hospital, and the distinguished visitor having replied the proceedings terminated. The annual dinner of the society took place after the meeting, at which Sir R. Douglas Powell, Lord George Pratt, Mr. de Paravicini, the Mayor of Windsor (Mr. W. Carter, J.P.), Dr. S. West, Dr. W. Hale White, Dr. Jamieson B. Hurry, and others were present.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The International Conference on Leprosy.

THE report of Dr. ARTHUR NEWSHOLME, medical officer of the Local Government Board, and Sir MALCOLM MORRIS, K.C.V.O., the delegates of His Majesty's Government to the International Scientific Conference on Leprosy held at Bergen from August 15th to 19th, 1909, has been presented to Parliament.

Bills Passed.

Amongst the measures which have passed during the present session, and have now received the Royal Assent, are the Local Education Authorities (Medical Treatment) Act and the Metropolitan Ambulances

Asylums Officers' Superannuation.

Several changes have been introduced into the Asylums Officers Superannuation Bill in committee of the House of Lords. At the instance of Lord BELPER an amendment was accepted substituting 20 for 15 years as the qualifying period of service, and 55 instead of 50 years as the age when an officer would be entitled to claim superannuation. A subsection was introduced to allow the visiting committees to grant to an officer permanently incapacitated by some injury specifically attributable to the nature of his duty a reasonable gratuity or special superannuation allowance

The Housing and Town Planning Bill.

When the Lords' amendments to the Housing and Town Planning Bill come before the House of Commons for consideration it is very likely that one or two of the provisions with regard to the medical officers of health of counties which have been struck out will be reinserted. Several medical Members of the House of Commons have, it is understood, pressed vigorously on the President of the Local Government Board the desirability of making these medical officers irremoveable without the consent of the Local Government Board. Mr. Burns, it is stated, is prepared to fall in with their views and to advise the House of Commons to reinsert the excised provision. On another point it is not

unlikely that something may be done in the hope of restoring still further the original terms of the clause dealing with county medical officers of health. The Lords struck out the powers given to the Local Government Board to prescribe the duties of these officers. In all probability, a compromise on this provision will be suggested which will make the county councils, and not their medical officers, the recipients of the communications of the Board in this regard.

Beri-beri on Merchant Vessels.

Several questions have recently been addressed by members of the Labour party to the representatives of the Board of Trade in the House of Commons on the occurrence of specific cases of beri-beri on British merchant vessels. For the most part the persons attacked by the disease have been Lascars. In answering one question on the subject Mr. TENNANT informed an honourable Member that the cause of beriberi had not yet been definitely ascertained, but there seemed to be no doubt that had and insufficient food predisposed to the disease. A full report of the inquiry in the specific case on which the question was based was communicated to the Royal College of Physicians of London, which body had the subject of beri-beri under investigation.

Tuberculosis Prevention in Ireland.

A petition from the Royal Sanitary Institute praying for further legislation with regard to the prevention of tuberculosis in Ireland has been presented to the House of Commons.

HOUSE OF COMMONS.

WEDNESDAY, OCT. 20TH.

The Naval Medical Service.

The Naval Medical Service.

Dr. V. H. RUTHERFORD asked the First Lord of the Admiralty whether his attention had been called to the acquittal of Fleet-Surgeon Charles Matthew by court-martial on a charge of behaving with contempt towards Commander Richard Walters, and also to the fact that Fleet-Surgeon Matthew was placed on the retired list at his own request on account of the charge; whether Commander Walters had retired; and what steps he was taking, in the interests of efficiency in the navy, to remove the alleged grievances of the Naval Medical Service.—Mr. McKenna replied: Yes, sir, Fleet-Surgeon Matthew has been placed on the retired list at his own request. Commander Walters has not retired. I should be glad if my honourable friend will direct my attention to the alleged grievances referred to in the last part of his question.

Dr. RUTHERFORD: Was a commission appointed to inquire into these alleged grievances?

Mr. McKenna: A committee was appointed to inquire into certain circumstances affecting the medical service in the navy, but I would not describe them as grievances.

Dangerous Hair-washes.

Sir WILLIAM COLLINS asked the Secretary of State for the Home Department whether he proposed to take any action with a view to restrict or prevent the use of substances for shampooing the hair which by reason of their poisonous or inflammable qualities were liable to cause serious injury or fatal results.

Dr. V. H. RUTHERFORD also asked the right honourable gentleman whether, in view of the recent further deaths which had taken

Dr. V. H. RUTHERFORD also asked the right honourable gentleman whether, in view of the recent further deaths which had taken place in the metropolis from the use of inflammable hair-washes, he could hold out any hope of the introduction of legislation next seesion for the purpose of prohibiting the use of such preparations.

Mr. Gladstore said, in reply to both questions: The matter is receiving my serious attention, and the question whether legislation ought to be undertaken will be fully considered. In the meantime, I may point out that, as intimated by counsel in the recent proceedings at Westminster police-court, the Director of Public Prosecutions would certainly prosecute for manslaughter if tetrachloride should again be used and a fatal result ensue. The inquest in the recent case of two deaths arising from the use of petrol is not yet concluded, but when the inquest is completed the question of prosecution will be considered by the Director of Public Prosecutions.

Guardians and Midwifery Orders.

Guardians and Midwifery Orders.

Mr. Henry Walker asked the President of the Local Government Board whether he had sanctioned the rules of some boards of guardians restricting midwifery orders to mothers who had already not less than a specified number of children; and, if not, whether he would express his official disapproval to the boards which had embo lied this restrictive provision in their rules.—Mr. Burns answered: The reply to the first part of the question is in the negative. I am aware that in the Minority Report of the Royal Commission on the Poor-laws and Relief of Distress attention is drawn to the rules of certain boards of guardians restricting the grant of mitwifery orders to mothers with a prescribed number of children. I have made inquiry on the subject, and I find that in some of the cases cited the rule is seldom or never acted upon, whilst in others it does not apply if the relief is given by way of loan. I am still giving attention to the matter.

Mentally Defective Persons in Workhouses.

Mentally Defective Persons in Workhouses

Mentally Defective Persons in Workhouses.

Mr. Henry Walker asked the President of the Local Government Board whether any legislation was being prepared in his department to give effect to the recommendations of the Royal Commission on the Care and Control of the Feeble-minded, with particular reference to the removal of mentally defective persons from the workhouses.—Mr. Burns said in reply: The initiation of legislation affecting the methods of dealing with mentally defective persons in public institutions would not be a matter primarily for my department, but the recommendations of the Royal Commission on the particular matter referred to in the question will not be lost sight of by me when any such legislation is proposed.

Infantile Mortality in Poor-law Institutions

Mr. HENRY WALKER asked the President of the Local Government Board, with reference to the statements in the Minority Report of the Poor-law Commission as to the absence of official statistics in regard to

the number of births in Poor-law institutions, the rate of mortality in Poor-law institutions of children between the ages of two and five years, Poor-law institutions of children between the ages of two and five years, and the rate of mortality under one year of age of infants being maintained on outdoor relief, whether he would request, by circular to boards of guardians or otherwise, that information on these several points should in future be collected and tabulated, with a view to its inclusion in one of the annual publications of his department.—Mr. BURNS replied: The recommendations made in the Majority Report and the Minority Report of the Royal Commission are receiving consideration. The recommendations in the former report as regards the development of official statistics cover a somewhat wider range than those in the Minority Report to which my honourable friend refers; and pending a decision on the whole matter I think it will be better to defer calling for any such special returns as are suggested in the question. question.

The Vaccination Order of 1907.

Sir MAURICE Levy asked the President of the Local Government Board whether the Vaccination Order of 1907, which came into force in October, 1907, had had the effect of reducing the total cost of vaccination, comparing the cost per vaccination before and after the Order came into force; and, if so, what the reduction had been.—Mr. Burns wrote in reply: There can be no doubt that the effect of the Order has been to reduce the cost of vaccination, but it would not be practicable to give the precise particulars desired by my honourable friend.

THURSDAY, OCT. 21st.

Medical Appointments in India.

Medical Appointments in India.

Mr. Rees asked the Under Secretary of State for India whether Eurasian military assistant surgeons lent to civil and medical departments in India were not generally statutory natives of India, and in that case equally qualified with natives of India proper for all and sundry appointments reserved for natives of India; and whether natives of India, Europeans, and Eurasians were as such in any way disqualified from employment in the civil medical department.—The MASTER or ELIBANK answered: The reply to the first question is in the affirmative, Indians are equally eligible with Europeans for admission to the Indian Medical Service, which service contains many Indian members. As to the civil medical department, I beg to refer my honourable friend to the papers recently presented to Parliament.

Mr. HAZLETON asked the honourable gentleman whether the India Office had received a resolution unanimously adopted at a meeting of the members of the medical profession, held under the auspices of the Bombay Medical Union, submitting that the present system of reserving all high and important posts in the medical service of India for military officers of the Indian Medical Service had led to the systematic exclusion of Indian medical men from them, no matter how highly qualified or deserving these Indian medical men might be; whether he was aware that the system in question had given rise to discontent and imposed unnecessary expense of over £100,000 on the Indian revenue; and what steps it was proposed to take in the matter.—The MASTER of ELIBANK replied: The Secretary of State has not received the resolution referred to. On the general subject I would refer the honourable Member to the correspondence recently presented to Parliament as to the steps that are being taken to promote the growth of an independent medical profession in India by throwing open to the profession in general some of the various civil appointments now held by officers of the Indian Medical Service and other similar appo

The MASTER OF ELIBANE: Both the Secretary of State and the

The MASTER OF BLIBARE: BOTH the Secretary of Source and and Viceroy are making inquiries.

Mr. Rees: Would not the expense of Indian administration be greatly increased if military medical officers were not engaged in civil employment in time of peace, inasmuch as a double set of officers would have to be retained?

No reply was given.

Carbon-Monoride Poisoning.

Carbon-Monoxide Poisoning.

Carbon-Monoxide Poisoning.

Mr. G. Roberts asked the Secretary of State for the Home Department whether his attention had been directed to a disease affecting certain workers in the printing trade, known as carbon-monoxide poisoning, arising from the fumes of a gas now being largely used in heating the metal pots attached to linotype composing machines; and whether he would cause an inquiry to be made with a view to the disease being scheduled as an industrial disease under the Workmen's Compensation Act.—Mr. Gladstone replied: I have made inquiry into the case of which the honourable Member has been good enough to send me particulars, and the reports would appear to show that it was a case of gradual poisoning by carbon monoxide. Such cases are extremely rare, and no other case of the kind in connexion with linotype work is known to the department. Poisoning by carbon monoxide is, of course, not uncommon, but it is almost invariably more or less sudden and of the nature of an accident, so as to come clearly under the main provisions of the Workmen's Compensation Act. The question of scheduling carbon-moxide poisoning as a disease was considered by the Industrial Diseases Committee, but they were unable to regard the evidence as sufficient to justify their recommending its inclusion. In view, however, of the present case, I will give instructions for the main provisors of the executive was considered to the recommending its inclusion. inclusion. In view, however, of the present case, I will give instructions for the matter to be carefully watched by the officers of the department.

Declarations under the Vaccination Act. 1907.

Declarations under the Vaccination Act, 1907.

Mr. Lupton asked the President of the Local Government Board whether he would ctate for what proportion of the births occurring from Jan. 1st to June 30th, 1909, were declarations made under the Vaccination Act, 1907, and how many declarations were actually made during that period.—Mr. Burns answered: The number of births in Ringland and Wales registered in the first two quarters of 1909 was 466,216. It cannot at present be stated in respect of how many of these children statutory declarations of conscientious objection to vaccination have been made. The number of declarations received by the vaccination officers during the first six months of the present year may be stated approximately as 88,500.

MONDAY, OCT. 25TH.

The Sewerage System of Kilkee.

Mr. A. LYNCH asked the Chief Secretary to the Lord Lieutenant of

Ireland, whether his attention had been called to the fact that the defective character of the present sewerage system in Kilkee had been the cause of considerable detriment to that town; and whether he could state what steps he was prepared to take with the object of providing a scheme for the establishment of a satisfactory sewerage system in Kilkee.—Mr. Birrell. replied: The question of the unsatisfactory sewerage arrangements at Kilkee has occupied the attention of the Local Government Board for a long time, and in 1904 it issued an order dealing with this subject and with the watersupply. Legal difficulties have, however, considerably delayed the Kilicush rural district council in procuring an improved water-supply without which new sewers could not be advantageously laid down. As the Board now understands that the new water-supply will shortly be in working order it has urged the district council to appoint an engineer and obtain plans for a sewerage system. In the event of unnecessary delay in proceeding with the works the Board will take steps to enforce its order.

Wednesday, Oct. 27th.

WEDNESDAY, OCT. 27TH.

The Poisons and Pharmacy Act, 1908.

The Poisons and Pharmacy Act, 1908.

Mr. Snowden asked the Secretary of State for the Home Department, whether he was aware that town councils were issuing, in lare numbers, licences to sell poisons under Section 2 of the Poisons and Pharmacy Act, 1908, in places where abundant facilities were provided by the shops of qualified chemists; and, in view of the statement made in that House by the Under Secretary when the Poison and Pharmacy Bill was under discussion, that licences would only be granted under Section 2 where reasonable facilities did not exist, would he take steps to stop the granting of such licences in violation of that understanding and to cancel such licences as had ben issued in contravention of it.—Mr. Gladetenk replied: I am afraid that I cannot add anything to the answers which I gave to questions whe honourable Member on this subject in June last. I have no power control the action of the town councils, and I have already called the attention of the Privy Council Office to the allegations made.

Salary £50, with board, lodging, and washing.

Staffordshire County Asylum, Cheddleton, Leek.—Senior Assistant Medical Officer. Also Junior Assistant Medical Officer. Salaries £250 and £200 per annum respectively, with board, apartments, and

washing.
STAFFORD, STAFFORDSHIBE GENERAL INFIRMARY.—Assistant House Surgeon. Salary £82 per annum, with board, residence, and

Surgeon. Sairy 202 per annum,
laundry

STAMFORD HILL AND STOKE NEWINGTON CHARITABLE DISPENSARY,
N.—Assistant Medical Officer. Sairy £100 per annum, with board
and residence.

STOKE-ON-TRENT. NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL, Hartshill.—Resident Surgical Officer, House Physician, and
Junior House Surgeon. Salaries £120, £100, and £50 per annum
respectively, with apartments, board, and washing.

SURREY DISPENSARY, Southwark, S.E.—Physician. Salary 50 guineas
per annum.

per annum.

Swindon, G.W.R. Medical. Fund Society.—Assistant Medical Officer, unmarried. Salary £300, advancing to £400 per annum.

Throat Hospital., Golden-square, W.—Resident House Surgeon.

Salary £75 per annum, with board, residence, and laundry.

Tunbridge Wells General Hospital.—Junior Resident Medical Officer. Salary £80 per annum, with board, residence, &c.

University College Hospital. Gower-street, W.C.—Resident Medical Officer, Surgical Registrar, and Obstetric Registrar.

Victoria Hospital for Children. Tite-street, Chelsea, S.W.—House Surgeon for six months. Salary £30, with board, lodging, and laundry. and laundr

and laundry.

WEST HERTS HOSPITAL, Hemel Hompstead.—House Surgeon. Salary £100 per annum, with rooms, board, and washing.

WESTMINSTER HOSPITAL, S.W.—Obstetric Physician. Also Assistant Obstetric Physician.

WEST SUFFOLK EDUCATION COMMITTEE.—Medical Inspector of School. Children. Salary £250 per annum, with travelling expenses.

THE Secretary of State for the Home Department gives notice that he proposes to appoint an additional Medical Referee under the Workmen's Compensation Act, 1906, for County Court Circuit No. 6, to be attached more particularly to Southport and Ornskirk County Court, and is prepared to receive applications for the appointment.

Births, Marringes, and Deaths.

BIRTHS.

CONSTANT.—On Oct. 25th, at Gravesend, the wife of Frederick Constant, L.D.S. Eng., of a son.
COOPER.—On Oct. 19th, at Hospital House. Pembroke Dock, to Surgeon Henry Cooper, Royal Navy, and Mrs. Cooper, a daughter.
LUMSDEN.—On Oct. 24th, at Fitzwilliam-place, the wife of J. Lumsden, M.D. of twin daughters.

M.D., of twin daughters.

PEARSON.—On Oct. 21st, at the Manor House, Leighton Buzzard, the wife of Reginald Spencer Pearson, M.R.C.S. Eng., &c., of a son.

PENNETATHER.—On Oct. 23rd, at Deanhurst, Harrow, the wife of C. Maxwell Pennefather, M.B., B.S., of a son.

MARRIAGES.

MARRIAGES.

Byles—Hamain.—On Oct. 25th, at Arras, Pas de Calais, France, James Beauzeville Byles, M.B., to Marie Alice Cecile, daughter of M. and Madam Hamain, France.

RLIS—Sanders.—On Oct. 19th, at St. Leonard's Church, Colchester, by the Rev. Canon Sanders, uncle of the bride, assisted by the Rev. J. M. Evans, Rector of Lexden, Frederick William Ellis, M.D., F.R.C.S. Eng., youngest son of the late Christopher Ellis of Penpol, Hayle, Cornwall, to Constance Maude Frances, eldest daughter of Edwin J. Sanders, of Lexden Park, Colchester.

Jackson—Ormerod.—On Oct. 20th, at St. Matthew's Church, Rastrick, Major R. W. H. Jackson, R.A.M.C., to Mary Beatrice, youngest daughter of the late C. J. Ormerod, Esq.

MASON—JACKSON.—On Oct. 27th, at St. Peter's, Little Thurlow, by the father of the bride, John Black Mason, M.B., Ch.B. Edin., of Ealing, to Edith Lilian, second daughter of the Rev. Robert Jackson, M.A., Rector of the parish.

MILBANK-SMITH—FORESHEW.—On Oct. 22nd, at St. Margaret's, Streatham Hill, Harry James Milbank Milbank-Smith, M.R.C.S., L.R.C.P., to Beatrice Ada, second daughter of Frederick Foreshew, Clapham Park, S.W.

WATSON—MACFARLANE—On Oct. 20th, at St. Mary's, Carden-place, Aberdeen, John Nuthall Watson, M.R.C.S., L.R.C.P. Lond., to Eleanor Gordon, third daughter of the late Alexander Macfarlane, H.M. Customs, and of Mrs. Macfarlane.

DEATHS.

Holman.—On Oct. 23rd, at Gate House, East Hoathly, Sussex, Thomas Holman, M.R.C.S., L.S.A., in his 72rd year.

Myers.—On Oct. 21st, at Kent Cottage, Cleveland-road, Ealing, Henry Reynolds Myers, V.D., late Surgeon-Colonel 19th, late 37th, Middlesex (Bloomsbury) Rifle Volunteers, in his 73rd year. Friends please accept this, the only intimation. Colonial and Egyptian papers, please coov.

papers, please copy.
REID.—On Oct. 25th, Charles Reid, M.B., C.M., aged 45 years.

N.B.- A fee of 58. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Rotes, Short Comments, and Answers to Correspondents.

HYPODERMIC PURGATIVES.

In the August number of the Journal of Pharmacology and Experimental Therapeutics Professor John J. Abel and Dr. L. G. Rowntree of the Johns Hopkins University contributed the first section of a paper on the pharmacological action of phenolphthalein and of some of its derivatives, with special reference to their behaviour as purgatives. An attempt was made to study the influence of substitution in various parts of the molecule upon the pharmacological and physiological properties of the phthaleins, more especially upon their excretion, reabsorption, and purgative action. Aside from these problems of theoretical and practical interest it was hoped that the investigation might lead to the attainment of a therapeutic endnamely, the discovery of a serviceable hypodermic purgative. The various experiments, which were made on dogs and rabbits. have led to results of considerable scientific and practical interest. They show that phenolphthalein and phenoltetrachlorphthalein do not differ markedly in their pharmacological behaviour. They are non-irritant when applied to mucous membranes or to open wounds, or when injected subcutaneously in oily solution. Their sodium and potassium salts, however, are highly irritating when administered subcutaneously in aqueous solution. The toxicity of these phthaleins is very low; large quantities may be injected repeatedly into a vein of the dog without causing any apparent pathological lesions; when given intravenously they cause a small and rather prolonged rise of arterial pressure. Both phenolphthalein and its tetrachlor derivative are laxative or purgative when given by the mouth or when injected under the skin or into a vein. When a solution of 0.4 gramme of the tetrachlor derivative in neutral olive oil is injected under the skin of dogs or of human beings a laxative action is induced which continues from four to six days. Phenolphthalein administered in the same dose and in the same way does not act for so long a time for the reason that it is more quickly excreted. This prolonged action, together with the low toxicity of these compounds, leads to the belief that a serviceable hypodermic purgative will be found among the phthaleins The tetrachlor compound is efficient as a or their derivatives. laxative, but its insolubility in water and its low solubility in oil stand in the way of its general adoption, although they do not detract from its efficiency when a subcutaneous laxative is required. It may be mentioned that in the various experiments on dogs it was held that the drug under trial had acted as a laxative when the free had changed from the clay-coloured, dry, and friable condition of the fore period to a brown or black, moist, homogeneous, sticky or pasty consistence. The experiments further show that the subcutaneous injection of an aqueous solution of the sodium salt of phenolphthalein. as suggested by Fleig, is impracticable owing to its irritating action, which is probably due to the liberation of sodium hydroxide in the tissues by hydrolytic dissociation. The success so is obtained in effecting purgation by the subcutaneous injection of an oily solution of the tetrachlor derivative of phenolphthalein The success so far without the production of local pain marks a distinct advance in therapeutics. Eserine and apocodeine are being used for this purpose to a limited extent in medical practice, but untoward results are frequently obtained with the former, while the latter, according to Heinze, cannot be depended upon in more than 47 per cent. of the cases. In hospitals for epileptics and the insane occasions frequently arise when a hypodermic purgative is needed, owing to the refusal of patients to take drugs by the mouth or in the form of an enema. This form of medication is also indicated in conditions of the digestive tract when administration by the mouth is impracticable, in comatose states, in cases where tolerance has been established to purgative given by the mouth, and especially in the practice of abdominal Turning to the mode of excretion of the phthaleins, the investigation shows that the tetrachlor derivative, when given subcutaneously, escapes from the body in the bile only. When phenolphthalein is given in the same way a part of it always escapes in the urine. When the tetrachlor derivative is administered by the mouth none of it appears in the bile or urine, but phenolphthalein, administered in a similar manner, may appear in both of these secretions to a small extent. As regards absorption by the large intestine, proof was obtained in several ways that after the subcutaneous administration of phenolphthalein and its tetrachlor derivative the mucosa of the large intestine absorbs these drugs from their solution in bile. It was also found that these compounds are not excreted by the intestines, except, perhaps, in minimal amounts.

AN INVALID BABIES' HOME.

A MEDICAL correspondent writes :-

"I believe I am correct when I say that there is not a convalence." home for babies under two years of age existing in England. This being so, I wish, through the medium of THE LANCET, to make more generally known a small home for babies which has recently been started by a community of Dominican nursing sisters it.

Bury St. Edmunds. I can testify to the excellence of their with

for whilst they were in London I visited the home. At that time the sisters had charge of four small children ranging from 18 months to two years old—one child had been taken from the Queen's Hospital, Hackney-road, a deplorable-looking little object with infantile hemiplegia, and two other little miseries from the slums of Hoxton, one of whom had been living in a cellar. They were all promptly put in the garden and kept there all day and made rapid progress and were to me a striking example of what fresh air, sunlight, plain and simple food will do for such cases. The children became fat and rosy, pictures of health. I am glad to have this opportunity of testifying to the careful and constant personal devotion to the little ones on the part of the sisters, who are hoping to extend their work, at present very limited as to numbers from want of funds. They will be glad to receive infants from one to three years of age suffering from rickets, paralysis (infantile and other forms), "wasters," and convalescents from acute diseases. A minimum charge of 5s. a week is made. I hope my confrères will make this work known, for I feel sure that such a home is very necessary and would probably be well supported were it known to exist. The address is, The Superioress, Home for Invalid Bables, 76, Guildhall-street, Bury St. Edmunds."

SMALL PROPERTY AND PUBLIC HEALTH.

Dr. G. W. Eustace of Arundel gave an address on "Why it is Difficult to Guard the Public Health," at a meeting of the Public Health and Local Government Officers' Association for Sussex, at Chichester, on Oct. 16th. In the course of his remarks he said there was an immense number of houses of the working classes which were unfit for human habitation, and the great difficulty was to bring them to the knowledge of the governing council. There was, he said, no machinery by which this could be done properly; it was done by disease after a man or woman or the children had gone to their graves. The medical officer's hands were tied because the working classes would not make complaint for fear of being turned out. Dr. Eustace is at the present time Mayor of Arundel, and in that borough, he said, a resolution had been passed that it should be the duty of the sanitary inspector to examine every house in the borough once in two years. The result, he added, had far exceeded what he expected, and in a great many cases some defect dangerous to human life was found. The difficulty which resulted from the condemnation of small property was that the tenants had no other place to go to, but Dr. Eustace thought that that was a difficulty which time must find some way to meet. In the subsequent discussion it was contended that the law did not go far enough and that sanitary authorities should have power to obtain an order from the justices for the closing of houses without serving a notice on the owner to abate the nuisance.

THE RELATIVE ACTIVITY OF NATURAL AND SYNTHETIC ADRENALIN (SUPRARENIN).

THE discovery of the vaso-constrictor action of the extract of the supra renal glands by Oliver, Schäfer, and others stimulated research into the chemistry of this valuable therapeutic agent, with the result that an active principle, more or less pure, was soon isolated by Abel, Aldrich, Takamine, and others. In proportion as this interesting substance was studied by physiologists and clinicians its field of usefulness was rapidly extended, until it has become recognised as one of the most useful drugs in the materia medica. Within the past few years synthetic methods have been discovered for producing bodies having the properties of adrenalin, including synthetic suprarenin, arterenol, homorenon, and other catechol derivatives. Of these the first named, a methylamino alcohol, was claimed by Biberfeld to be physiologically identical with the natural substance. Dixon and Cushny, however, found that these substances did not possess equal activity, and evidence was soon obtained that the synthetic substance was optically inactive, being a mixture of the dextro- and lavowas optically inactive, being a mixture of the dextro- and lavorotatory bases, of which the latter alone was markedly active, thus supporting Cushny's conclusion that the natural base, which is lavo-rotatory, is twice as active as the synthetic base. Later, Cushny examined specimens of the dextro- and lawo-varieties of the synthetic base and found that their physiological activity was in the ratio of 12:1, while the lawo-rotatory synthetic base was about equal in potency to the active midually extends from the clarks. principle obtained from the glands. The manufacturers of the synthetic product, however, do not appear to have allowed Cushny's work to pass unchallenged, with the result that during the past few months the question has been in an unsettled condition. In view of the great importance of the matter it is satisfactory to note that an investigation has been conducted by Dr. W. H. Schultz, in the pharmacological laboratory of the Public Health and Marine Hospital Service of the United States, and the results are published in the form of a bulletin (No. 55) of 77 pages. One of the first difficulties encountered was the variation in the activity of the natural substance (adrenalin) found upon the market. A quantity was purchased direct from the maker, and after re-purification it was found to contain only 31 per cent. of the pure base, whereas the maker had claimed that it contained 77 per cent. In comparing the activity of the various substances Dr. Schultz determined the rise of blood pressure in dogs under morphine-ether anæsthesia, the vagi being cut, and sufficient curare being given to prevent tremor of the muscles. The determination of the mydriatic action of adrenalin and its substitutes upon the frog's eye, when exposed to bright sunlight, afforded trustworthy results, but the reaction is less delicate and more tedious than th,

blood-pressure method. He found that the optically inactive synthetic suprarenin possesses only two-thirds of the vaso-constrictor and mydriatic properties of the natural substance. It is interesting to note that isolated experiments might be taken from those recorded by Dr. Schultz to show that both Biberfeld and Cushny were correct. A comparison of successive sets of readings, however, shows that Cushny's results were more nearly correct than those of Biberfeld. Of the other catechol derivatives arterenol was found to be equal in activity to the natural substance, while homorenon possesses but one-Experiments made on mice to eightieth the activity of either. Experiments made on mice to determine the relative toxicity of these substances showed that the natural product is one and a half to twice as toxic as the optically inactive synthetic substance, five times as toxic as arterenol, and from 80 to 88 times as toxic as homorenon. In conclusion, Dr. Schultz suggests that the relative physiological activity of these catechol derivatives seems to depend upon a substance partaking of the properties of a secondary alcohol or ketone, upon the nature and number of groups displacing the hydrogen of the amino group, and upon the arrangement of the asymmetric carbon atom in space. With the theory that these are the determining factors in modifying the vaso-constrictor action of such compounds, it is hoped that as a working basis it will aid in a more extended study of other compounds possessing similar physiological activity.

OUR DEADLY ATMOSPHERE!

THE following words form the last paragraph of an article in the Paily Mail, headed "Scientists in a Boiler," describing certain physiological experiments with high atmospheric pressures at the London Hospital Medical College:

"An important point which has been elucidated by these experiments is that the poisonous factor in the atmosphere, nitrogen, is absorbed five times faster by the fat than by any other tissue in the body, and that, therefore, fat men are peculiarly unsuited to act as divers, workers in compressed air caissons, etc., for their liability to absorb nitrogen with undue rapidity makes them fall ready victims to heart and circulatory troubles when working under such conditions.

Doubtless we shall soon be supplied with a nitrogen-free atmosphere now that the attention of the authorities has been called to the poisonous properties of that inert gas in which mankind has been immersed for so many centuries.

A HYGIENIC TABLE-FORK.

To the Editor of THE LANCET.

SIR,-I have read with much interest the notice in your issue of Sept. 18th of an invention with this title. Had this invention been given to the world some 20 years ago the career of a poor lad who has since been often in my mind would not have been blasted.

In the spring of 1889 I started housekeeping in a small settlement on the Portuguese coast of West Africa, and the servant problem was one of many with which I was faced. For the household work I was obliged to hire some juvenile slaves from their masters, and of these, to whom fell the duty of cleaning the knives and forks, was a dusky youth who, from his striking profile, the palmated form of his feet, and the unpronounceability of his own name, was rechristened by me "Pato Ganso"—or "The Goose." He was a well-meaning boy, but I could not disguise from myself the fact that the forks too often showed traces of what appeared to be the previous meal lodged in the angles between the prongs, and I felt it my duty to seek an interview with him while he was at his work. I found him busy at his table. On one side of him was a pile of "dirty" forks, on the other was a smaller heap of "clean" ones. Pressed firmly between his lips was a fork thrust well home into his enormous mouth. Ryeing me with the steadfast and contented gaze of a menial who has by chance been caught doing his work conscientiously and well, he slowly but firmly withdrew the fork and placed it on the clean" pile. Still regarding me with the respectful air of a good and faithful servant he took up a "dirty" fork and, to the apparent imminent danger of his uvula, proceeded with the cleansing process-Before this was completed, however, he was, to his bewilderment, sent back to his master, who relegated him to agricultural labour, to the hardships of which he, doubtless, succumbed in due course, Had a hygienic fork been in existence in those days The Goose might by now have attained the dignity of a butler's position, and I should have been spared many a retrospective shudder.

I am, Sir, yours faithfully, NIGEL KEN.

Bombay, Oct. 5th, 1909

CONVICTION OF A BIRD-BLINDER.

THE practice of blinding birds with the superstitious motive of improving their powers of song is unbappily common enough in Southern Europe, but it is very rare to hear of a case being proved in this country, although it is generally known that English birdfanciers exist who are brutal enough to do it. On Monday last Frederick Collins was sentenced to three months' hard labour at Lambeth police court for destroying the sight of two chaffinches. According to the Times report, Mr. Alexander Pearce, a veterinary surgeon, said that he had examined the birds, and in one case both eyes were disorganised; in the other only one eye seemed to have been tampered with. He was of opinion that the optic nerve and the

central artery of the retina had been severed by inserting a needle at the back of the eye. An officer of the Royal Society for the Prevention of Cruelty to Animals (which instigated the prosecution) deposed that the defendant had confessed to him that he had blinded the birds, "but it was a dangerous word to use." He also said, "At my game you have to be a tectotaler. You want a very steady hand with the needle." The defendant protested his innocence, but received The defendant protested his innocence, but received the sentence stated above. Cruelty of this kind can only be appraised by its motive, and as the motive that makes bird-blinders is simply the desire for gain, there are few punishments that can be considered excessive for them

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Beek.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION (Hon. Secretaries—J. Gray Duncanson, H. Charles Cameron): at 4.30 p.m.

Papers:
Dr. David B. Lees: The Physical Signs of Incipient Pulmonary
Tuberculosis and its Treatment by Continuous Antiseptic
Inhalations, with the Results in 30 Cases.
Dr. H. H. Dale: The Action of Some Diuretics.

PATHOLOGICAL SECTION (Hon. Secretaries—L. S. Dudgeon, C. Bolton): at Royal Medical College, Millbank, at 8.30 P.M. Laboratory Meeting.

LARYNGOLOGICAL SECTION (Hon. Secretaries—George C. Cath-cart, L. Hemington Pegler): at 5 p.m.

LaryngoLogical Section (Hon. Secretaries—Greerge C. Caurcart. L Hemington Pegler): at 5 p.m.

Mr. Seccombe Hett: (1) Chronic Glanders in a Man aged 24 Years; (2) Three Specimens of Neoplasms of the Palatine Tonsils, and One of the Pharyngeal Tonsil, Removed by Operation: Microscopic Sections of the Growth; (3) An Attachment to v. Bruning's Instrument for Facilitating Manipulations under Direct Laryngoscopy.

Dr. Dan McKenzie: Perforation of the Nasal Septum from Salt (NaCl) Dust in a Woman aged 20 Years, and Specimen prepared by Dr. Wyatt Wingrave.

Dr. StClair Thomson: (1) Tuberculosis of Left Vocal Cord and Inter-arytenoid Space, in a Lady aged 46 Years, Completely Healed by 2 Months' Silence and Sanatorium Treatment; (2) Tuberculosis of the Larynx in a Medical Man, aged 41 Years, Developing after Sanatorium Treatment, and Cured by Galvano-cautery; (3) Tuberculosis of the Epiglottis, Left Aryepiglottic Fold and Left Inter-arytenoid Space in a Gentleman, aged 47 Years, Completely Healed by Galvano-cautery and Sanatorium Treatment; (4) Papilloma of the Larynx in a Boy, aged 64 Years; 4 Years' Duration, Cured by Tracheotomy and repeated Operations by Direct Laryngoscopy; (5) Enchondroma of the Larynx in a Woman, aged 58 Years, Removed by Laryngo-fissure.

- (5) Enchondroma of the Larynx in a Woman, aged 58 Years, Removed by Laryngo-fissure.
 Dr. Jobson Horne: Laryngeal Neoplasm in a Woman, aged 64 Years—brought before the Section on Nov. 6th, 1908, when a Microscopic Section was also exhibited.
 Mr. Stuart-Low: A Case of Extra-laryngeal Inoperable Carcinoma, shown at Meeting on May 7th, and shown again to Illustrate Beneficial Effects of Operation on Thyroid Gland.
 Dr. Dundas Grant: (1) Neoplasm or Infiltration (Tuberculous) of Left Ventricular Band Concealing Left Vocal Cord; (2) Epithelioma on Posterior Surface of the Cricoid Cartilage, Simulating Tuberculosis, in a Woman, aged 29 Years, Operation for Complete Laryngectomy begun but abandoned on account of Extensive Involvement of Œsophagus; (3) Epithelioma of the Right Vocal Cord in a Man, aged 60 Years, Removal by Thyrotomy; (4) Epithelioma of Left Vocal Cord in a Woman, aged 58 Years, Removal by Thyrotomy.
- Thyrotomy.

 Dr. Dundas Grant and Dr. Dan McKenzie: Epithelioma of Left Vocal Cord in a Woman, aged 58 Years, Removal by

Vocal Cord in a Woman, aged 58 Years, Removal by Thyrotomy.

Dr. Irwin Moore: Paralysis of Left Recurrent Laryngeal Nerve existing for 21 Years in a Male, aged 57 Years.

Dr. Clayton Fox: Paralysis of the Vocal Cord in a Case of "Myotonia Atrophica."

Mr. E. B. Waggett: Case Illustrating the Evil Effects of Prolonged Use of Cocaine in the Nose.

Dr. Scanes Spicer: Model by which the Variation in Effect of Costal (back) and Abdominal (belly) Breathing on the Stresses, Strains, and Frictions in the Throat and Larynx, more especially of Cricoid Cartilage on the Spinal Column, and also the Transverse Axis of Respiratory Rotation of the Cricoid on the Thyroid Cartilages, can be Illustrated.

SECTION OF ANÆSTHETICS (Hon. Secretaries—Llewelyn Powell, R. W. Collum): at 8.30 p.m.

Paper:
Dr. Vivian Orr: Heart Massage in Chloroform Syncope.

Dr. R. H. Hodgson: An Apparatus for the Administration of Ether by the Open Method.

N.B.—Fellows of the Society are entitled to attend and to speak at all Meetings.

NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales's Hospital, Tottenham, N.

THURSDAY .- 4.15 P.M., Clinical Meeting.

RÖNTGEN SOCIETY, 20, Hanover-square, W.

THURSDAY. -8.15 P.M., Ordinary General Meeting.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East,

Tuesday.—5 p.m., Dr. J. A. Lindsay: Darwinism and Medicine. (Bradshaw Lecture)
THURSDAY.—5 p.m., Sir T. Clifford Allbutt, K.C.B.: Greek Medicinein Rome. (Fitz-Patrick Lecture.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn. Fields, W.C.

Monday.—5 p.m., Prof. S. G. Shattock: Sarcoma. (Museum

Demonstration.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. G. Little: Clinique (Skin). 5.15 P.M.,
Lecture:—Dr. G. E. Herman: Puerperal Belampsia.

TUESDAY.—4 P.M., Dr. J. Taylor: Clinique (Medical). 5.15 P.M.,
Lecture:—Dr. Purves Stewart: Facial Hemispasm.

WEDNESDAY.—4 P.M., Mr. A. P. Gould: Clinique (Surgical). 5.15 P.M.,
Lecture:—Dr. A. E. Giles: The Menopause, Natural and
Artificial.

Artificial.

Arthecial.

THURSDAY.—4 P.M., Sir Jonathan Hutchinson: Clinique (Surgical).

5.15 P.M., Lecture:—Dr. L., Guthrie: Some Nervous Affections in Children.

FRIDAY.—4 P.M., Dr. J. Horne: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-

oad, W.

MONDAY.—10 A.M., Lecture:—Surgical Registrar: Demonstration of
Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays.
Mr. Dunn: Diseases of the Eyes. 2.30 P.M., Operations. 5 P.M.,
Lecture:—Mr. R. Lloyd: Amesthetics.

TUESDAY.—10 A.M., Dr. Moullin: Gynæcological Operations.
12.15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M.,
Medical and Surgical Clinics. X Rays. Dr. Davis: Diseases
of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr.
Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr.
Moullin: Gynæcological Cases.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children.

Moullin: Gynacological Cases.

WEDNESDAY.—10 A.M., Dr., Saunders: Diseases of Children.
Dr. Davis: Diseases of the Throat, Nose, and Ear. 12.15 p.m.,
Lecture:—Dr. G. Stewart: Practical Medicine. 2 p.m., Medical
and Surgical Clinics. X Rays. Mr. B. Harman: Diseases of
the Ryes. 2.30 p.m., Operations. Dr. Robinson: Diseases of
Women. 5 p.m., Lecture:—Dr. Low: Examination of Blood
in Tropical Diseases.
Thursday.—10 A. Lecture.—Surgical Positions. Description.

in Tropical Diseases.

THURSDAY.—10 A.M., Lecture:—Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Pathological Demonstration:—

Dr. Bernstein. 2 p.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eyes. 2.30 p.M., Operations. 5 p.M., Lecture: Mr. Edwards: Clinical.

FRIDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. Medical Registrar: Demonstration of Cases in the Wards. 2 p.M., Medical and Surgical Clinics. X Rays. Dr. Davis: Diseases of the Throat, Nose, and Rar. 2.30 p.M., Operations. Dr. Abraham: Cases Diseases of the Skin. 5 P.M., Lecture:-Dr. Abraham: Cases of Skin Diseas

of Skin Disease.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Mr. B. Harman: Diseases of the Eyes. Dr. Davis: Diseases of the Throat, Nose, and Ear. 12.15 P.M., Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. 2.30 P.M., Operations.

Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. 2.30 P.M., Operations.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed seclusively "TO THE EDITOR," and not in any case to any gentileman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTI-FICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANOET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES. TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are :-

FOR THE UNITED KINGDOM.
One Year £1 12 6
Six Months 0 16 3
Three Months 0 8 2
Three Months 0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANGET Offices, 423, Strand, London, W.O.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address— THE MANAGER, THE LANGET OFFICES, 423, STRAND, LONDON, ENGLAND.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND Co., 51, Fifth Avenue, New York, U.S.A.

DARWINISM AND MEDICINE.

Delivered at the Royal College of Physicians of London on Nov. 2nd, 1909,

By JAMES ALEXANDER LINDSAY, M.A., M.D. R.U.I., F.R.C.P. LOND.,

PROFESSOR OF MEDICINE IN THE QUEEN'S UNIVERSITY OF BELFAST; PHYSICIAN TO THE ROYAL VICTORIA HOSPITAL, BELFAST,

MR. PRESIDENT AND GENTLEMEN,—I trust I may with some propriety in this year of the Darwin centenary ask you to consider with me the significance of Darwin's great discovery for medical thought and practice. The subject is large and can on this occasion be dealt with only in outline. The field which I shall ask you to traverse is a well-trodden one, but I believe its fruitfulness is not yet exhausted. Darwin's work on "The Origin of Species" contained, as Helmholtz said, "an essentially new creative thought," a thought, I venture to add, which is still fertile, still seminal, still full of suggestion and guidance for all whose labours lie in the field of biology.

The relation of the science and art of medicine to the higher thought of the day must always be a matter of interest and importance. Medicine is coloured by that thought; its postulates, prepossessions, and theories are modified by it; in its degree it contributes to that thought. When we get from the facts of science to the truths of science, to emphasise a pregnant distinction, our thinking is modified, stimulated, or deflected to an important extent by the intellectual atmosphere in which we live. A notable instance in point is afforded by the Father of Medicine—Hippocrates. In the Homeric poems everything is miraculous. The storm, the sunshine, shipwreck, plague, blight, sickness, victory, defeat—everything is due to the direct interposition of supernatural powers. "Every event," as the late James Adam said, "is a theophany." The conception of natural law has not yet arisen. How different is the atmosphere of the works of Hippocrates. Here, amidst much that is crude and empirical, there is a genuine recognition that in the field of disease events follow a natural sequence, that effects are proportionate to causes, that order reigns, and that our business is to investigate that order. Between Homer and Hippocrates had intervened the great school of the Ionian physicists from Thales to Democritus, physical science had seen its dim and feeble dawn, the lineal succession was opened which was one day to include the names of Copernicus and Galileo, of Leibnitz and Newton, of Darwin and Wallace. The comparative failure of the successors of Galen to advance the art of medicine, and the barrenness of our art during the many hundred years during which their influence reigned supreme, were due in large measure to the false philosophy which lay at the root of the Galenic system, to the predominance of metaphysical theory over observation and experiment. rapid advance of medical science in modern times has coincided with the progress of physical and biological science in general, in part because science furnishes medicine with instruments of precision and methods of research, but perhaps even more because it creates the atmosphere in which medicine can flourish and develop. The reaction of one branch of science upon another branch at the present day is both potent and prompt.

I need not inform you that the conception of evolution existed long before Darwin and goes back to the very dawn of science. It is said to occur in the sacred books of the Vedas; it was the central thought of the philosophy of Heraclitus; it is found in the works of Aristotle, and we can trace it through a long succession of thinkers, including Bacon, Descartes, Leibnitz, Hume, Kant, Goethe, Buffon, Geoffrey St. Hilaire, Erasmus Darwin, and Lamarck. It is interesting to note that one of the most notable precursors of Darwin was a member of our own profession—Dr. James Cowles Prichard of Bristol. Writing in the year 1826, Prichard clearly recognised the existence of organic evolution; he fully apprehended that domesticated races of animals and plants have been produced by selection by man

and not by the influence of environment; he recognised the operation of natural selection, though he misinterpreted its range and importance; and, most curious of all, he recognised the difference between acquired and congenital characters and argued for the transmissibility of the latter and the non-transmissibility of the former-a view reached independently half a century later by Weismann and now usually associated with his name. Darwin did not discover evolution. He discovered its leading law, and by a long series of observations, experiments, and reflections, unparalleled in the history of science, converted the brilliant guesses of earlier inquirers into an assured truth and an established principle. "We claim for Darwin," says Alfred Russel Wallace, "that he is the Newton of natural history, and that, just as surely as that the discovery and demonstration by Newton of the law of gravitation established order in place of chaos and laid a sure foundation for all future study of the starry heavens, so surely has Darwin, by his discovery of the law of natural selection and his demonstration of the great principle of the preservation of useful variations in the struggle for life, not only thrown a flood of light on the process of development of the whole organic world, but also established a firm foundation for all future study of nature. The conception that the organic world is the scene of an incessant struggle, of a keen vital competition in which the fittest survive-i.e., the fittest for their environment in the capacity to obtain food, resist their enemies, and propagate their kind—while the unfit perish, has been recognised as the fundamental law of life, and the demonstration of this principle we owe to Darwin and to Wallace. As Weismann says, this principle "has become the basis of the science of life," it "has conquered the world," and has become so inwrought in the texture of our thought that it is now practically impossible to think of any biological problem except in terms of evolution. That any of the fundamental features of the Darwinian doctrine have been subverted by 50 years of inquiry and controversy is not to my mind a tenable proposition. It is true that some of the subordinate features of that doctrine remain open questionshow far, for example, use and disuse have operated in producing organic changes, what weight is to be assigned to the influence of the environment—a point upon which careful readers of the works of Darwin will see that his mind wavered from time to time-what is the precise significance and area of operation of sexual selection, whether acquired characters are inherited or not, how far the Mutationism of De Vries and others operates instead of slow and almost imperceptible change. On these points finality has not yet been attained, but their solution—whatever it may be—will not invalidate the Darwinian doctrine. The general tendency of inquiry since Darwin's time has been, upon the whole, to strengthen the claim of Natural Selection to be regarded as the great law of organic life, to show how wide its range, how subtle its operations, and to minimise the importance of othes factors. To take an example—at first sight nothing can be more obvious than to attribute to the effect of disuse the loss of sight by fish, crabs, and rats inhabit-ing the dark caves of Kentucky and Carniola. But another view is at least tenable. When, owing to the absence of light the faculty of sight ceased to be of utility to these creatures. Natural Selection, of which the function is to keep every organ which is of use to any creature up to the mark, ceased to operate, and it is a fundamental law that any organ withdrawn from the conservative action of natural selection tends to degenerate. The controversy especially associated with the name of Weismann, whether acquired characters are inherited or not, is one of vast and far-reaching importance for practitioners of medicine. Weismann, as you are aware, holds that in all organisms there are two kinds of plasm, the somatic and the germinal, that the permanent germ-plasm passes unchanged through a series of generations and is not affected, or but little affected, by environmental influences, which affect the somatic plasm; that modifications produced upon the somatic plasm by the environment and by use or disuse are practically limited to the individual and not transmitted to the offspring, and that hence no characters except those predetermined in the germ are available for evolution. This question is too large to be discussed at any length on this occasion. Medical opinion has been to a large extent opposed to the views of Weismann, but it must be admitted that he has succeeded in throwing great doubt on the transmissibility of acquired characters, a doctrine which Darwin

No. 4497.

be possible.

assumed as too obvious to require demonstration. Most of the supposed cases of such transmission are apparent rather than real. Syphilis seems a crucial case in point, hereditary syphilis being one of the most familiar of phenomena. But it is now practically certain that this is not a case of inheritance at all, in the strict sense of the term, the true explanation of the facts being an ante-natal infection of the ovum, usually from the maternal side. Whether tuberculosis is ever directly conveyed from parent to child is still doubtful, but if such transmission were proved the most probable explanation would be the direct inoculation of the embryo and not inheritance. To disprove Weismann's doctrine, we should require to show that mutilations or the results of training, exercise, or education, or acquired diseases, reappeared in the offspring as the result of heredity. has not been hitherto conclusively shown. The problem is one which has great interest for us, and medical observers might contribute to its solution. May I suggest a case in point where evidence from the side of medicine might be available? In a certain proportion of cases neurasthenia is brought on by over-study, anxiety, overwork, want of sleep, excess of some kind, in persons where no congenital tendency to nervous disease can be suspected. Is such neurasthenia transmitted either as neurasthenia or some allied condition? The question is worthy of attention and an answer ought to

Darwin as a scientific worker presents us with a model good for all time, and worthy of admiration and imitation. "My success as a man of science, whatever this may have amounted to," he tells us, "has been determined by complex and diversified mental qualities and conditions. Of these the most important have been a love of science, unbounded patience in long reflecting over any subject, industry in observing and collecting facts, and a fair share of invention and common sense." In another place he says, "Whatever I have done in science has solely been by long pondering, patience and industry." This is altogether too modest an estimate. Darwin, in point of fact, possessed in a supreme degree two faculties rarely present in perfection in the same individual-viz., immense industry and accuracy in the accumulation of facts and a daring originality of speculation, coupled with much caution in drawing any final conclusions. He had the power of keeping any subject more or less before him for a great many years. He was an indomitable theoriser and held that "without speculation there is no good and original observation." Again he says. "I cannot resist original observation." Again he says, "I cannot resist forming a hypothesis upon every subject." The essential fairness and integrity of his mind is shown by the following passage: "I had also during many years followed a golden rule—namely, that whenever a published fact, a new observation or thought came across me which was opposed to my general results, to make a memorandum of it without fail and at once, for I have found by experience that such facts and thoughts were far more apt to escape from the memory than favourable ones.'

May I suggest that in much of the above there is a wholesome lesson for ourselves? That we should be diligent, patient and thorough in the collection of facts goes without saying. That we should keep those facts for long periods, even for years, before our minds before drawing, still less publishing, our conclusions will seem a hard saying to the contributors to periodical medical literature. Perhaps, indeed, such a rule is a counsel of perfection, hardly possible to the average man. But I would ask you to note the high place assigned by Darwin to theorising and speculation in This may seem a dangerous doctrine, but I am convinced that it is a sound one. Medical science is to-day overweighted by the accumulation of a vast array of more or less crude and isolated facts. What we need is the illuminating generalisation, the daring hypothesis, to coördinate facts hitherto out of relation with each other, to give perchance to science a new organon, to light the way to fresh fields of inquiry and discovery. It is the presence of this element of underlying theory or law which lends so much attractiveness to the work of Pasteur and Lister, of Koch and Metchnikoff, of Ehrlich and Wright. The bold hypothesis lights up the dark ways of nature, illumines the road already traversed, sheds light on the pathway which lies ahead.

Before proceeding, after the foregoing more or less preliminary observations, to apply the principles of Darwinism to man in health and in disease, I may be permitted to

remind you of the fundamental Laws of Growth which must guide us in our inquiries. These laws might be stated as follows: (a) the law of the perpetuation of species or of the unity of type; (b) the law of variation; (c) the law of reversion; (d) the law of atavism; (e) the law of correlation, whereby when one organ varies other organs tend to vary also; (f) the law of compensation or economy, whereby increase of growth of one organ is accompanied by diminution in growth of another organ; and (g) the law of sexual selection.

We might summarise the foregoing laws as follows: The general tendency in all living organisms is that the child shall resemble the parent in specific characters—i.e., that the unity of type shall be preserved. But variation from type is always present to a greater or less degree. Darwin thought that variation was largely due to changed conditions of life. Weismann believes that sexual reproduction is the chief cause of variation in the higher animals, including man, and Wallace shares this view. Variation is accompanied by a tendency to revert to type. Hence, notable departures from type tend to die out, but to this law there are many curious exceptions—e.g., the Ancon sheep and the numerous "sports" amongst plants which have given rise to permanent new varieties. Atavism is the law whereby the child sometimes resembles the grand-parent or the greatgrand-parent more than the parent. It may be regarded as a special case of reversion. By the law of correlation we mean that principle whereby when one organ varies another organ varies, the two organs not always being related in function. Thus white cats with blue eyes are always deaf. In certain breeds of cattle colour and susceptibility to the attacks of flies are correlated. By the law of compensation or economy we mean that principle whereby nutriment required by the overgrowth of one organ is withdrawn from another organ. It is probably in consequence of this law that the highly specialised reactions of the nervous system developed in an advanced stage of civilisation are accompanied by a decline in the birth-rate. Finally, sexual selection is undoubtedly a factor, although much uncertainty exists as to its extent of range and importance. The comparative absence of hair from the human body, especially in the female sex, has been attributed with much probability to sexual selection.

DARWINISM AND NORMAL HUMAN STRUCTURE AND FUNCTION.

Man is a member of the animal series, and it is reasonable to expect that the ordinary laws of evolution would be exemplified in his structure and in his functions. This we find to be the case. The body of man is built upon the same lines—bone for bone, muscle for muscle, artery for artery—as that of the higher apes. The comparatively few distinguishing features of the human organism have relation to three points-viz., the assumption by man of the erect posture, his acquisition of special manual dexterities, and his higher cerebration. The foot, the hand, and the fore-brain are almost the only points with regard to which the human body differs essentially from that of the quadrumana. Evolution accounts easily and adequately for these differences. Let us look at a few points less obvious than these. Why out of every score of human beings are about 19 right-handed and 1 left-handed? On any creationist hypothesis this question admits of no plausible answer, but evolution suggests a highly probable explanation of the We may fairly assume that as man developed and his functions became more specialised it was necessary that certain parts of his structure should acquire special dexterities, and that it was by the law of economy that these dexterities were concentrated upon one limb instead of being shared by both. Hence were developed the special manipulations of the right hand. But the law of variation above mentioned would suggest that in a matter of this kind evolution would not act with undeviating uniformity, but would admit of certain departures from type. And so we find, as we might have anticipated, that about 1 person in 20 is left handed. That the special dexterities of the right hand are not innate and predetermined but the result of development is shown by the fact that the left hand contains potentially the same aptitudes as the right, and these aptitudes can be successfully developed when the right hand is lost as the result of accident or disease.

explanation, first suggested I believe by Moxon, is that by the same law of economy it was in the interest of the developing organism that the centres presiding over the mechanisms of speech—the precise significance and mode of operation of these centres are not here in question-should be located in one rather than in both hemispheres. It is entirely in accord with this theory that the right side of the cerebrum should contain potential speech centres, and that these should be capable of successful and adequate development when the centres on the left side are destroyed by disease. It is also quite in line with evolutionary doctrine that the same side of the cerebrum should preside over the fine manipulations of the right hand and the complicated motor mechanisms of

Why are the teeth so often crowded together in the human jaws that the removal of some of them is often a necessity in early life? Evolution affords the probable clue. There are good grounds for concluding that the human jaws are undergoing a progressive diminution in size. This diminution should be accompanied by a corresponding diminution either in the size or number of the teeth, but it is quite in accord with experience in other departments that the two processes should not proceed pari passu. Apparently the diminution in the size of the jaws has outrun the diminution in the size or number of the teeth, and hence the overcrowded state of the jaws which we know to be common. This explanation is adequate and probable, although it might be argued that the teeth are of less utility to man now than in earlier ages, and are hence partially removed from the operation of natural selection.

Many of those whom I address must sometimes have reflected over the curious and apparently clumsy arrangement whereby our food and drink before entering the gullet have to pass over the entrance to the air passages, involving a slight but appreciable risk of foreign matters finding their way into the lungs—a risk slight in health but sometimes serious in disease. The explanation suggested by evolu-The explanation suggested by evolutionary law is that the lungs have been developed from the swim-bladder of an unknown progenitor, and that an organ originally adapted for flotation has been developed as an organ of respiration. The relation of the swim-bladder to the gullet would not have involved the same risks as the relation of the gullet to the air passages. If we accept the alternative view of the origin of the lungs—viz., that they have been developed from a pair of gill clefts—the same explanation will apply.

Why is the septum between the auricles of the heart so imperfect that the passage of blood from one chamber to the other is only just obviated in the normal individual, while patency of the foramen ovale is one of the commonest of malformations? May it not be that we have here an example of imperfect and not yet completed development? May we not expect that the present valvular arrangement for preventing the flow of blood from one auricle to another will in the course of time, under the influence of natural selection, be converted into a permanent and complete septum?

DARWINISM AND RUDIMENTARY ORGANS.

Perhaps on no subject has evolution thrown a more welcome or a more satisfying light than upon the significance of rudimentary organs. At first sight, nothing can be more puzzling than that there should be in the human body certain organs which are functionally useless to the indi-Of such organs we have the following:—(a) The panniculus carnosus, corresponding to the muscles which move the skin in the lower animals. There are some persons who possess the power of moving at will the skin of the scalp and other parts, and I believe the music-halls once possessed an artist who earned an honest livelihood by exhibitions of his power to throw plates and other articles from his head by contractions of the scalp muscles. (b) The ear muscles, functionally inactive in most individuals, but in exceptional cases capable of causing movements of the pinna, suggestive of the great importance of the movements of that organ to the lower animals. (a) The animal ear-point, a projection upon the outer fold of the ear, present in some persons and corresponding in position to the pointed ear of many animals. (d) The rudimentary nictitating membrane or plica semilunaris. (e) The vermiform appendix, functionless in man but of great importance in some of the vegetable feeders amongst the lower animals. (f) The foramen supraoondyloidean.

In addition to the above there are certain organs which seem in process of becoming rudimentary and functionless. Cutaneous hairiness is no longer of service to man, and will probably disappear under the operation of natural selection, perhaps assisted by sexual selection. The third molar or socalled wisdom teeth are probably becoming functionless. They pierce the gums late, or in some cases not at all, and they are prone to early decay. It seems probable that the sense of smell, no longer of much practical importance to civilised man, and hence removed from the action of natural selection, is becoming rudimentary. The human toes, with the exception of the great toe, which is of service in maintaining the upright posture, being no longer organs of prehension and almost functionless, are undergoing elimination.

Rudimentary organs present no difficulty to the evolutionist. They are simply belated survivals of organs once functionally important to the race, but now on their way to extinction and disappearance. No longer under the conserving influence of natural selection they are very prene to vary and to become the seat of disease. We see this law well exemplified in the case of the vermiform appendix, which is both highly variable in structure and very subject to disease.

It has been suggested that the many feet of the human intestine are simply survivals from a herbivorous progenitor and of no service to a mixed feeder like man. It has even been proposed that the aid of surgery should be invoked to curtail some of its superfluous folds, which, it is argued, are not only useless but actually a source of danger. On such a delicate subject I prefer to express no opinion. Modern surgery does not need to be stimulated to fresh fields of enterprise—least of all by a physician.

The bearing of evolution upon physiological processes opens up a wide field for reflection and speculation. We are so apt to regard these processes as fixed and final, while in reality we should regard them as fluid, variable, undergoing a process of adaptation rather than as completely adapted, imperfect but under the influence of natural selection tending towards perfection, or in some cases, perhaps, exhibiting traces of reversion. The phenomena of digestion, for example, will appeal to our intellect and imagination very differently according as we regard them as ultimate and final facts or as part of an evolutionary process. Man has gone through many phases in the matter of his food, and it is likely that he has still in this department a journey to go. Perhaps it might savour of irony to suggest that vegetarianism is a case of reversion to the habits of remote herbivorous ancestors, but the idea is one worth thinking over. When we are urged to lessen our consumption of butcher's meat and to rely more upon nuts and salads, the question arises how far carnivorous habits are for man in the natural line of development, how far he should regard himself as essentially a mixed feeder, how far reversion to the dietetic habits of earlier ages would be a gain or a retrogression. The really illuminating thought amongst these somewhat difficult problems is that the habits of man are not predetermined and final, but the result of countless generations of evolution, that they are neither wholly good nor wholly bad; that, on the one hand, they are worthy of respect as having stood the test of an immense experience, while, on the other hand, they are almost certainly destined to important modifications in the future. In this case, how-ever, as always, natural selection and adaptation to the environment will be the guiding principles to which man in his arduous march through time will be compelled to

DARWINISM AND DISEASE.

What light can evolution throw upon disease, upon its origin and course, upon the response of the organism to its assault, upon immunity and proclivity, upon the principles and results of treatment? On all these heads something might be said, but the issues thus raised are too farreaching to be adequately dealt with on the present occasion.

An inquiry into the origin of disease in the biological sense may well seem futile. How the first bacillus of tubercle or the first plasmodium of malaria came into being may be plausibly regarded as a problem as mysterious and as futile as the origin of matter or the origin of life, questions which Darwin always refused to discuss. "It is mere rubbish," he says in one of his letters, "thinking at present of the origin of life; one might as well think of the origin of matter."

14

-1

Yet the origin of life has provoked many speculations, inconclusive but not absolutely vain and sterile. The origin of a morbific micro-organism can be only dimly surmised, but evolution may help us to understand how such organisms have acquired their potency for mischief. In some cases e.g., tuberculosis—there is reason to believe that civilisation and the habits of civilised man have had much to do in conferring toxicity upon an organism comparatively innocuous under more primitive conditions of existence. Many facts of bacteriology suggest to us that organisms such as the pathogenic bacteria owe a large part of their virulence not so much, as it were, to their inherent properties as to certain conditions of growth which are only very partially known to us. If this view be sound, it will follow as an obvious corollary that tuberculosis is to be suppressed, not by destruction of the bacillus, but simply by depriving it of those conditions necessary for its growth and development.

Evolution may throw some light upon the different effects which the same etiological factors are known to cause in different individuals. Over-indulgence in eating and drinking produces in one individual gout, in another cirrhosis of the liver, in a third renal disease, in a fourth arterio-sclerosis, and so on. How are we to account for the different responses to the same stimulus? We have to assume some congenital peculiarity in the individual, the result of factors which may stretch back to a remote past and which have been developed in accord with evolutionary laws. A similar train of reflection is suggested by the facts of immunity, a subject upon which so much brilliant work has been done in recent years. The precise mechanism of immunity, the action of phagocytes, alexins, or other protective agencies need not here be dwelt upon. The effects of food, temperature, fatigue, of previous diseases, of protective inoculation whereby the specific protective substances have to be formed in the body itself, and of immunisation by transference of protective substances previously formed in antitoxic serum, are well known to you. What seems clear is that when full account has been taken of all secondary causes of immunity we are thrown back upon a factor which we may vaguely describe as "constitutional" "congenital," or as a personal peculiarity or idiosyncrasy. Why does one individual fall a ready prey to scarlet fever or diphtheria while another resists repeated exposure to contagion? It is of great interest to learn that certain protective agencies are at work, which can be, to a certain extent, recognised. But it is clear that the recognition of such agencies only pushes the problem farther back, and does not finally solve it. That the predisposition to contract infective disease, or to resist infection, runs strongly in families is a matter of daily observation. Some people, as the saying is, "catch everything that is going," others escape though equally exposed to infection, and these peculiarities are found to characterise certain stocks and strains. Again, some persons on being infected quickly develop all the usual consequences of infection, while others develop them slowly, or imperfectly, or even not at all. We are familiar with the fact that the bacillus of diphtheria may be present in the fauces of healthy individuals who have been in close contact with sufferers from the disease and no further development occur. It is probable that most of us at some time or other have received the bacillus of typhoid fever into our systems, in most cases without injurious result. I may even suggest to you that some persons have tubercle bacilli in their sputum and seem very little, if at all, the worse for their presence. These facts might be multiplied indefinitely, and they all point in one direction—viz., that when all the secondary agencies of immunity have been unveiled—and the inquiry into them is one of extraordinary interest and importance—we shall still be left with some unexplained factor, some congenital or hereditary element which has arisen in accord with evolutionary law. We have facts which suggest to us that civilised nations are undergoing a process of gradual immunisation to infective disease. When measles was first introduced into the Faroe Islands and the Fiji Islands, there was an enormous mortality, amounting in some cases to one quarter of the entire population, while subsequent epidemics have shown a much lessened virulence. In accounting for such facts there seem to be two possible theories—(1) that certain inhabitants of these islands possessed a special susceptibility to the toxin of measles, or (2) that the population as a whole in some way developed

an acquired immunity, of course to an incomplete extent, against the disease. The extraordinary virulence of Asiatic cholera when it first penetrated from its original home in Bengal to Europe and America is a phenomenon of the same category, while its declining severity in subsequent invasions, which is so often attributed solely to improved hygiene and greater caution regarding food and water, may really be due, in part, to the operation of an evolutionary law. Why are negroes so resistant to yellow fever, so susceptible to tuberculosis and small-pox? May it not be that the explanation is evolutionary, that the negro has been longer in contact with the first-mentioned disease than with the remaining two, and has hence acquired a certain degree of immunity against it? Why are Anglo-Saxons in India so much more susceptible to typhoid fever than the native inhabitants? Is it because the latter, inhabiting a country where hygienic laws are so little recognised, have developed a considerable degree of immunity? Or is it, as some affirm, that a large proportion of the native inhabitants suffer from mild attacks of typhoidfever in youth, and hence are protected during the rest of their lives? Tuberculosis is rapidly declining amongst nearly all civilised nations. Is this exclusively the result of improved hygiene, a higher range of comfort, better houses, better food, or is it, in part, the effect of a gradually developing immunity? Further, it may be asked, Are the two views really incompatible one with the other? How far is an acquired immunity due to improved methods of living? Again we may ask, Is the growing sobriety of civilised nations the result of a gradually developing immunity against the injurious effects of alcohol? Are the drunkard and the intemperate undergoing a process of slow but sure elimination?

My object is not to affirm any dogmatic opinion on these important issues, but to suggest to you that in our thinking on these matters we must take a wide and philosophic view; we must recognise that in disease great secular processes, as well as more concrete casual factors, come into view. The present generation of medical workers and observers is somewhat impatient of those conceptions of "diathesis" and "temperament," which meant so much to our predecessors. We are disposed to think that these ideas lack definiteness and concreteness, that they are too vague to be of any real utility. Yet a study of evolution in its bearing upon disease may suggest to us that these terms, vague though they are, adumbrate a great truth-viz., that in proclivity to infection and response to disease nothing is so potent as what we vaguely call "constitution," "temperament," "here-ditary tendency," and the like. We have been intent upon the "search for the microbe," a search which has already yielded brilliant results, and, it is needless to say, must be continued. But the response of the organism is an element at least as important as the presence of the toxin. In the future it may turn out that we shall be compelled to devote less attention to the seed, more attention to the soil.

Evolution is capable of throwing a flood of light upon many of the most familiar phenomena of disease. We are apt to accept these phenomena as ultimate facts, as the effects of a toxemia or of some other obvious casual factor. But it is possible to push the analysis a little deeper, to trace the true inwardness of morbid phenomena a little farther back. Let us ask the question, How does it happen that in an ordinary case of hemiplegia the arm suffers more than the leg or the face, and in the arm, why is it the finer movements of the fingers and hand should suffer more than the coarser movements of the elbow and shoulder? It is easy to answer that the reason is anatomical and relates to the seat of injury and the distribution of fibres in the internal capsule, but this explanation needs itself to be explained. Here, again, we may without extravagance invoke evolutionary law to help us. The fine manipulations of the hand and fingers are in all probability the last to be acquired by the developing organism, they are the least stable acquisitions of nervous tissue, they are the first to suffer under the shock of disease. The nervous system, as it were, most easily forgets the lesson most recently learnt, just as the old man forgets the events of yesterday while he remembers those of 50 years ago. Aptitudes recently acquired in the genetic series are less ingrained, as it were, in the nervous system than those which go back to an earlier stage of development. Dr. Hughlings Jackson long ago pointed out the order of the dissolution of function in the brain when under the influence of alcohol. The first to go are the highest faculties—judgment, memory, taste. In the next stage speech becomes affected; it becomes thick and indistinct. Next the emotions are involved; the individual becomes hilarious, maudlin, or quarrelsome. Last of all, the centres of organic life, respiration, circulation, deglutition, are affected, and death may ensue. Now, this order of events is not fortuitous. The nervous functions, under the influence of a narcotic poison undergo dissolution in a definite order, the order of development, which corresponds to the order of complexity and specialisation. It is probable that this law will be found to have a somewhat wide application in the field of disease. General paralysis of the insane is a good case in point, the elements of character and judgment usually suffering before those of voluntary movement.

That the laws of evolution and the influence of heredity throw light on the response of the organism to disease will, I think, be generally admitted. We are not wrong in attaching weight in prognosis to any known family tendency in connexion with any given case of disease. It helps us in forming some estimate of that subtle and intangible but most potent element which we vaguely call "the resisting power of the individual." In many cases of disease we give the first place in prognosis to what is termed "the observed tendency of the individual case." This is not a truism, though it may sound like one. Let me take an illustration. A patient presents himself with the signs and symptoms of slight incipient tuberculous infiltration of one apex, and the question of prognosis arises. We know that the disease may either undergo early and complete arrest, or develop to a certain extent and then undergo regressive fibrotic change, or progress to softening and excavation, or become rapidly disseminated throughout the pulmonary area. It is quite out of our power to predict with certainty which of these events will happen, but in attempting any forecast nothing is more helpful than attention to the family history, on the one hand, and, on the other hand, to "the observed tendency of the individual case," which time alone can reveal. We are dealing with the power of resistance which the individual can offer to the action of the tubercular toxins, and that power is part and parcel of the individual's heredity and constitution "-it is developmental and evolutionary.

It has been debated whether there is any such force as a vis medicatrix nature. Many have regarded the existence of this force as obviously written on the face of nature, while others have denied even its existence. Can evolution throw any light upon this question? Nothing can be more certain than that nature tends to revert to the normal. In another connexion Francis Galton calls this "the law of regression towards mediocrity"; in other words, the tendency is for the abnormal to disappear and for the unity of type to be preserved. Darwin thought that this law had a wide application and was even inclined to believe that tall men often married short women and that clever men often married silly women-nature's unconscious protest against the abnormal and unconscious striving to preserve the unity of type. If such a law exists we might argue without paradox that disease is the abnormal and that on the broad grounds of evolutionary law we might expect the tendency to be to eliminate the abnormal and to return to the normal. That tendency may, of course, be too weak successfully to resist the forces in opposition to it.

DARWINISM AND RACE PROBLEMS.

Let us now turn to a field where by general consent the influence of evolution has been potent. The "survival of the fittest "—a term first suggested by Herbert Spencer—and its correlative the "elimination of the unfit," have been generally accepted as expressions which succinctly sum up the effects of the operation of natural selection. It is important to remember that "fittest" does not mean best, either physically or ethically. It simply means fittest for the conditions of existence in any given case, most fully adapted to the environment, best able to succeed in the struggle for existence. Evolution does not necessarily involve progress, though the general law is progression from the lower to the higher, from the less to the more specialised. "Everything depends upon adaptation," says Weismann, and Höffding reminds us that "adaptation and progress are not the same." Degeneration is as truly evolutionary as progress, the upward and the downward movement being both the result of adaptation. Further, evolution does not postulate that organs and

organisms are perfectly adapted to their present needs and conditions. They may be in process of becoming perfectly adapted. Natural selection, Darwin reminds us, tends only to make each organic being as perfect as, or slightly more perfect than, the other inhabitants of the slightly more perfect than, the outer management same area with which it comes into competition. When same area with which it comes into competition. When selection," says Hugo de Vries, "acts as a sieve; it does not single out the best variations, but it simply destroys the larger number of those which are, from some cause or other, unfit for their present environment. In this way it keeps the strains up to the required standard, and in special circumstances may even improve them." The conditions of racial efficiency, as defined by the laws of evolution, would seem to be the following: (a) the race must become progressively adapted to its environment, and by environment we mean climate, food-supply, and competition in the struggle for existence; (b) there must be competition and struggle, leading to elimination of the unft, otherwise degeneration will take place; and (o) there must not be too much in-breeding, and each strain must be from time to time crossed by another and allied strain. To this last law there are, however, some curious exceptions. When we compare man with the lower animals in these regards we are at once struck with some obvious points of contrast. Man is not subject to the unrestrained operation of natural selection. He wears clothes and builds houses to protect himself from the storm and the cold. He brings food from farthest East or remotest West to make up for the deficiencies of the home supply, and he lays up stores against the day of famine. He protects the repro-ductive function by law and custom. He restrains the warlike instinct and keeps it within bounds. He prevents or cures disease, makes life possible for the feeble, the ailing, and the malformed, and even gives them the opportunity of propagating their kind. He cherishes the aged and enables them to prolong their days. By some of his laws—e.g., the law of primogeniture—he sets the principle of natural selection at defiance. In these and other ways the ordinary usages of civilised society run counter to the operation of natural law, and it becomes an anxious question whether civilisation in so doing does, or does not, contain the seeds of its own dissolution. Rousseau and his school believed that civilisation involved degeneration. Evolution was not within the purview of their thought, but we cannot evade the issue,—Does evolution strengthen the contention which these thinkers reached by a process of intuition, whether true or false?

We hear much to-day of the degeneracy of the nation, and the existence of such degeneracy is assumed by many writers. The question is, however, one of extreme complexity. It is almost impossible to obtain the data for a just comparison as regards physical fitness between the present and preceding ages. On the one hand, the ratio of defectives, including deaf and dumb, lunatics, epileptics, paralytics, infirm, &c., is said to have increased from 5.4 per 100 over 15 years in 1874 to 11.6 in 1896. On the other hand, there are some encouraging facts. The average duration of life is increasing. Some of the worst scourges of the human racetuberculosis, typhoid fever, malaria-are abating their severity, the sick-rate of our benefit societies is declining. But these facts are not irreconcilable with the possibility of

physical degeneracy.

In the absence of conclusive data on this crucial question we may ask whether any light is obtainable from the study of evolutionary law. Are there any analogies from plant or animal which may contain suggestion for us? Domestication amongst plants and animals is the analogue of civilisation amongst men. The effects of domestication are, however, exceedingly complex. In some animals—e.g., the bear family and carnivorous birds-domestication leads to sterility; in others—e.g., sheep, pigs, and barn-door fowl—domestication seems to increase fertility. Many flowers become double under cultivation and continue fertile, while other double flowers lose their power of producing seed. Some highly-bred animals develop a marked delicacy of constitution and become very liable to disease. In some plants an artificial increase in the richness of the soil tends to the production of wood-fibre rather than of flower and seed.

On the whole, the above facts do not help us. The main question remains, Does civilisation, by preserving the unfit and preventing their ruthless elimination which takes place in a state of nature, imperil the physical integrity of the race? Our marriage customs, for example, the not uncommon conjunction of youth and beauty with age and wealth, the transmission of enfeebled constitutions and sometimes of actual disease from parent to child, can such things be tolerated without grave risk to the physical welfare of humanity? Is the medical profession free from serious responsibility when it preserves those whom Nature has plainly marked out for elimination, and even enables them to transmit their unfitness to their descendants? These are not extravagant or sentimental questions. They are, on the contrary, highly practical questions, and if we so often keep them out of sight l suspect it is from an uneasy subconsciousness that they involve painful and paralysing issues.

That civilisation runs counter to natural selection is, I think, evident. It interposes artificial barriers to the free play of those forces which in a state of nature give the victory, both as regards personal existence and opportunity for perpetuating the species, to the strong, the brave, the fit. But it is not to be assumed without argument that civilisation is dependent upon natural selection. According to Lloyd Morgan, "Natural selection has long ceased to be the dominant factor in human progress." The same view is propounded by J. B. Bury in the following passage: "It may be said that, so far as concerns the actions and movements of men who are the subject of recorded history, physical environment has ceased to act mechanically, and in order to affect their actions must affect their wills first, and that this psychical character of the causal relations substantially alters the problem. Most thinkers now agree that the chief clues to the growth of civilisation must be sought in the psychological sphere. Imitation, for instance, is a principle which is probably more significant for the explanation of human development than natural selection." is the view of a historian, and it must be admitted that it contains a great deal of truth, though not the whole truth. Mankind is more dependent for its progress upon the brain of a Pasteur or a Lister, a Kelvin or a Marconi, than upon the muscles of many cricketers, footballers, or oarsmen. The puny, sickly, or deformed child, which in a state of nature would be promptly eliminated, may possess the brain of a great discoverer, poet, or statesman. Yet physical soundness can never be ignored or deemed of small significance.

If physical degeneration is going on in our midst—and who can deny the fact, however much we may differ as to the extent of the fact?—we may feel sure that it is due to some species of non-adaptation to the environment. are inclined to attribute such degeneration as exists mainly to unwholesome surroundings, bad housing, bad air, bad food, insufficient exercise, and unsuitable clothing. These factors have weight, perhaps much weight, but a study of the phenomena of evolution may well make us doubt whether they are really the heart of the problem, whether, after all, the main thing is not that we are, to a more or less extent, breeding from the wrong stock. Few men have had less reason than Darwin to retract any opinion once definitely formulated, few have been from first to last more consistent in their views, but it is clear that Darwin wavered much and wavered often as regards the weight to be assigned to external conditions—climate, food, occupation—as factors of evolution. He was at one time inclined to attribute very little weight to such conditions in comparison with natural selection; later in life he was disposed to assign greater importance to them. Some of his followers have regarded shall not attempt to pronounce, but I shall content myself with the contention that race degeneracy, where it exists, is not to be satisfactorily explained by the operation of temporary and transitory causes, but must be sought in the most profound laws of growth and survival.

Let us look at another racial problem in the light of evolutionary law—viz., infant mortality—which we are all agreed is excessive. Is infant mortality due simply to bad hygiene, unsuitable food, careless mothering, or is it in any sense the analogue of the terrific waste which we know to go on in nature? Stand under one of our forest trees and watch the clouds of pollen which fall around. How many of these granules ever reach an ovule? In a well-known passage Tennyson tells us of the sad misgivings which

the spectacle of the portentous waste in nature excited in his breast—

"Are God and Nature then at strife, That Nature lends such evil dreams? So careful of the type she seems, So careless of the single life;

That I, considering everywhere Her secret meaning in her deeds, And finding that of fifty seeds She often brings but one to bear, I falter where I firmly trod"

Tennyson understates the case. Nature exhibits an amazing, a sinister prodigality of increase and of destruction. A single flesh-fly, Wallace informs us, produces 20,000 larvæ, which reach their full size in five days, so that each parent fly may be increased ten-thousandfold in a fortnight. A pair of our common birdsthrush, blackbird, sparrow, titmouse -if allowed to live and breed unmolested, would have in ten years no less than 20,000,000 descendants. The machinery of destruction is, however, in a state of nature not less efficient than the machinery of growth and increase. It is a somewhat melancholy reflection that a similar law is at work amongst mankind. We may recognise this law without proposing to acquiesce in it. In this instance, as in others, we shall find that civilisation and natural selection run counter to each other. As civilisation advances the birth-rate falls. This is, apparently, a universal law, complicated though it may be by local conditions or national habits. The birth-rate is steadily falling amongst our own nation, and even more decidedly in France and America. In the former the fall has been sufficient practically to arrest the natural increase of population. A phenomenon of this kind, apparently world-wide in its operation, and one that could not have been anticipated, must depend on evolutionary law. Herbert Spencer is inclined to think that intellectual development and the reproductive faculty have to a certain extent an inverse ratio to each other, and that the rapid increase of the population of the world—"Even slow-breeding man," Darwin tells us, "has doubled in 25 years"-will be arrested as civilisation develops. I cannot detain you with any of the ethical problems which such a view suggests. I must content myself with pointing out how evolution seems to be operating, how profound is its influence, and how mistaken we shall probably be if we attribute such large facts as a falling birth-rate solely to temporary and wholly preventable causes.

The relation of the medical profession to the question of the propagation and preservation of the unfit raises many difficult questions which cannot be adequately considered on this occasion. The question of our responsibility to those who shall come after us, though not a new ethical problemit is found in Plato-has become a practical question only in modern times. It is a principle with which we have hence-forth to reckon. The art of medicine was for thousands of years concerned solely with the cure or relief of disease. At the present day the prevention of disease bulks hardly less largely in our thought, and this point of view indicates a distinct advance. In the future one may predict with confidence that the preservation of the purity of the race will be regarded as one of the essential tasks of the art of medicine. The whole question, it is almost needless to say, is involved in the greatest difficulty, but it will certainly force itself increasingly upon our attention. It will do so with the greater insistence if we realise that the future physical well-being of the race will be determined more by natural selection than by attention to environment, important though this latter factor may be. That the medical profession will ever in this country be invested with disciplinary powers for the regulation of marriage seems doubtful. Such control would probably be foreign to the habits of mind of the British race, but we see that attempts have been made in this direction in some of the States of the American Union, and to a lesser extent in Germany, with what degree of success I am unable to say. It seems probable that in this country we shall have to rely upon the operation of an enlightened public opinion-enlightened, as it must be, to a large extent by the influence of the medical profession.

Is the human form destined to undergo important changes in the future under the operation of evolutionary law? Are we to look for the coming of the super-man, a conception with which the thought of Nietzsche has rendered us

familiar? "What with man is the ape?" says Zarathustra. "A joke or a sore shame. Man shall be the same for Beyond-man, a joke or a sore shame." This is by no means certain. Weismann thinks it doubtful whether man may not have achieved the summit of his development both as regards physique and intellect, and is inclined to look for progress solely in the ethical sphere. Yet some of the facts adduced in this address seem to point decisively to the conclusion that the human body is destined in the course of many generations to undergo at least minor changes. The teeth, the hairy covering of portions of the body, the toes, the special senses are almost certain to undergo modification. Nor can we limit the probability of change to such parts as these. All we can say in this connexion is that the changes which will come will be the outcome of evolutionary law. Useless organs will be eliminated. Useful organs will undergo progressive adaptation to altered conditions, such as diet, climate, habit, occupation. The possibility of reversion and of degeneration will always need to be reckoned with.

A general survey of the relation of Darwinism to the science and art of medicine is likely, I think, in many ways to be salutary. It will certainly tend to breadth of view, to a philosophic appraisement of the factors with which we have to deal, to a recognition of the great underlying laws and secular processes which are related to our art. It may. perhaps, act as a damper upon enthusiasm when we realise that evolutionary change is slow and only partially under our control; but, if this be the truth, it is better for us to know and to recognise it. Medicine will gain in stability and in influence, as well as in dignity, by being in close relation with the higher thought of the day. It may in some not unimportant particulars react upon that thought. Disease becomes something more than a disagreeable and embarrassing fact when we realise how closely it is related to evolutionary processes, how vivid is the light it is capable of throwing upon evolutionary law. It even takes its place, a temporary place we may hope, in the eternal order. "Harmonious order," says Huxley, "governing eternally continuous progress; the web and woof of matter and force interweaving by slow degrees, without a broken thread, the veil which lies between us and the infinite—that universe which alone we know or can know—such is the picture which science draws of the world."

ON OXALURIA AND THE TREATMENT OF CALCIUM OXALATE DEPOSIT FROM THE URINE,

WITH A METHOD FOR THE SOLUTION OF CALCIUM OXALATE CALCULUS WHILST IN THE URINARY PASSAGES, ¹

By ROBERT MAGUIRE, M.D. Lond., B.Sc. Vict., F.R.C.P. Lond.

It is proposed to discuss in this paper: (1) Certain matters concerning the nature and mechanism of oxaluria in general; (2) a case which illustrates some of these and also oxalate stone formation, and in which it is claimed that an oxalate stone was dissolved in the urinary passages; and (3) some laboratory experiments in which the same process was successfully repeated in vitro.

It is known that the fresh normal urine contains a certain amount of oxalic acid which can be determined as such after destruction or alteration of its salts. Its amount is small and by no means easy of estimation, but has been fixed, more recently by Dunlop, at a medium of 0.0172 gramme for the 24 hours secretion. Calcium also in comparatively loose combination is present in the normal urine in quantity variously estimated at about 0.3 to 0.4 gramme in the daily output. The affinity between this acid and this base is so keen that if they exist together in solution combination must be assumed to occur unless some powerful influence should intervene. Again, calcium oxalate is so extremely insoluble in water or in a solution of ordinary salts, so dilute as is the urine, that the compound would be expected to show itself as a deposit in

A paper read before the Medical Section of the Royal Society of Medicine on Oct. 26th, 1909.
 Journal of Pathology and Bacteriology, vol. iii., p. 389.

3 Monthly Journal of Medical Science, 1849, ix., p. 943.

one of its well-known crystalline forms, octahedra or dumbbells, immediately after the urine is passed. Yet the normal person shows no such regular deposit of calcium oxalate from his urine, although from time to time those who have no other apparent departure from health, excrete urine which throws down a crystalline shower of this salt. Such deposits may be nothing more than a portion of the physiological content of the urine, extruded under the influence of illunderstood or unknown alterations of physical suspension or chemical solution. Not infrequently such showers alternate with others of crystalline uric acid, suggesting that each may have its cause in an alternating disorder of metabolism. Further, these small, vagrant, and alternating showers of calcium oxalate on the one hand, and of uric acid on the other, are at times accompanied by slight nervous and dyspeptic symptoms, scarcely severe enough to attract the attention of their subject, usually, like the deposits, of short duration, and having no apparent connexion with the general health. Yet they must be due to a disordered mechanism and in higher degree may be of more serious import. Obviously it is important to know the connexion, if any, between these symptoms and the crystalline showers, and also why the very insoluble calcium oxalate, small in amount though it be, is held up in ordinary urine, and yet at times deposited. The conditions institute the conditions are the conditions and yet at times deposited. just described do not overpass the limits of healthy variations, but may easily do so. The normal small excretion of oxalic acid, in spite of certain views to the contrary, is probably an accident or incident in the metabolism carbon, towards a higher or a more oxidised form. If there should occur such changes in the body mechanism as would cause an excessive production of calcium oxalate or its immediate precedents rather than of an otherwise developed and soluble carbon compound, then the normal means for maintaining calcium oxalate in solution in the urine would be overcome and deposit would be permanent. Calciumoxalate is practically insoluble in any solutions except those of the mineral acids, yet it may form no deposit in the presence of acid phosphate of sodium, to which the acid reaction of the urine is due. It is probably this salt which holds up from precipitation the small amount of calcium oxalate present in normal urine, and it continues to do so even if the acidity be neutralised. The exact method by which this is brought about is unknown, but I suggest that we have to do, not with an ordinary process of solution, but with the formation of a soluble double salt of the two bases. Dunlop thought that other substances in the urine might have a similar effect, but he was unable to find them. Any precipitation of oxalate of calcium in the urine, beyond the slight occasional showers mentioned above, must, I believe, be due to an exaggerated production and isgenerally accompanied by an exaggeration of the nervous and dyspeptic symptoms. The deposit and the symptoms were grouped together by Begbie³ into a "symptomen-complex" under the name of oxaluria. Usually the symptoms have been thought to be the result of the conditions. producing the deposit, but it is one object of this paper toshow that the oxaluria is sometimes at least caused by the dyspepsia, and that this in turn is produced by nervous overstrain, of which the nervous symptoms are an indication. In some cases and, as I would maintain, in that to be presently described, nervous and physical strain is the primary factor, causing atony of the stomach and colon and a dyspepsia. with obscure chemical results; the chemical changes which occur as the result of the dyspepsia then lead to metabolic disorders which result in the excessive secretion and deposit of calcium oxalate in the urine.

The association of a dyspepsia with oxalate urinary deposit has many times been insisted upon, but never, as I think, satisfactorily explained. Dunlop asserts that it is simply an acid dyspepsia with excessive secretion of hydrochloric acid, which favours the absorption of oxalic acid from foodstuffs. This assertion appears from his paper to be based on nothing more than a resemblance between the symptoms of such acid dyspepsia and those met with in oxaluria, an unreliable groundwork for an opinion. Against it is the fact that the dyspepsia which accompanies oxaluria is usually of the atonic variety, and, as in the case to be described, the stomach may be relaxed and dilated. Such a condition is not associated with excess of hydrochloric acid,

but rather with fermentation and a late dyspeptic formation of lactic, butyric, and other fatty acids from decomposition. Dunlop gives two experiments to show that also lactic acid favours the absorption of oxalic acid from foodstuffs, but the conditions of the experiments were very different from those which obtain when lactic acid is produced in a dilated stomach by decomposition and fermentation some time after a meal. On the other hand, atonic dyspepsia with its accompaniments, and also true acid dyspepsia, in by far the majority of cases, are unattended by a deposit of oxalate from the urine, no matter what the diet may be, while again oxaluria and even calcium oxalate calculus may at times occur without any symptom of dyspepsia having been perceived. For this reason I remark that the dyspepsia when present has obscure chemical results, upon which the copious literature of the subject gives absolutely no information. Yet in many cases, as in that to be discussed, a causal relation between the dyspepsia and the oxaluria can scarcely be doubted.

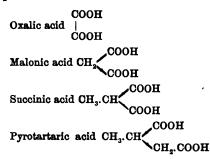

The primary source of the deposited calcium oxalate has been much discussed, and most of the numerous views upon the subject which have been published may be thus summarised: (1) Uric acid may by decomposition be transformed into oxalic acid, either within the system, or in the urine after it has passed the kidneys; (2) the oxalic acid may be produced from gelatine or mucus, either introduced with the food or formed in the stomach; (3) the oxalic acid contained in a large number of foodstuffs is simply absorbed and resecreted; and (4) deficient oxidation causes retarded metabolism of any or all the foodstuffs, and so brings about the production of oxalic acid instead of a more highly evolved compound.

All these views have been argued pro and con by many authors, mostly with insufficient facts at their disposal, but the last view, that of retarded metabolism, first put forth by Beneke,4 has been the most generally accepted, and seems to be at least the most consistent with the clinical phenomena. Of recent years, however, the third view-that the oxalate is derived from the oxalates of the foodstuffs-which was originated by Cantani, and supported in this country by Dunlop, has received renewed attention. Its principal basis seems to be that a larger number of vegetables than we suspected contain calcium oxalate, and that a purely meat diet (Cantani), a purely milk diet (Dunlop), or a diet of bread without crust (Esbach 6), will cause the disappearance from the urine of calcium oxalate deposit which had previously been found. Obviously, the premisses are at least uncertain, for it may equally and even better be argued that these diets have simply removed the dyspepsia whose peculiar chemical results have caused the formation of oxalic acid. Further, other observers, especially Auerbach, Wesley Mills, and Petterutti, have found even a considerable amount of oxalate deposit in the urine after a diet entirely devoid of Toepfer 10 contributes an interesting though not conclusive observation. He ascertained that in one of the large hospitals of Vienna not more than 5-6 per cent. of the patients showed any oxalate deposit in the urine. On certain days the general dietary for all patients contained spinach, sorrel, or other vegetables in which there is a considerable quantity of oxalic acid, yet on those days there was no increase of oxalate deposit amongst the patients.

Those who hold the "alimentary oxaluria" theory seem to assume, whenever the point is in any way mentioned at all, that the oxalate of calcium is absorbed from the stomach, passed as such into the blood, and carried as such to the kidneys, to be there simply excreted. But Owen Rees, 11 whose view of the production of oxalate from already excreted uric acid was probably wrong, held strongly that it was impossible for such an insoluble salt to exist in the blood, and here he was certainly correct. There is a mechanism for maintaining a small amount of calcium oxalate in solution in the urine,

but this does not exist in the blood, and if it did it would be powerless to maintain in solution for carrying purposes the larger amount found in the urine in oxaluria, when the mechanism of the urine itself is overpowered. Insoluble calcium oxalate can no more pass through the walls of the stomach than through those of the kidney, and still less can it exist in the blood. The presence of oxalate of calcium in the stomach, on the one hand, no matter how introduced there, and in the urine on the other, even in relative quantities, is no argument for the supposition that there is a direct connexion by the blood between the two "loci" of the salt without the intervention of an intermediary compound. Nor is it less improbable that the intermediary compound is oxalic acid itself or one of its soluble salts. There are only two facts which even apparently support such a view. Sir Alfred Garrod 12 found calcium oxalate in the serum of a blister, but his patient was already suffering from the uric acid diathesis, Bright's disease, and pleurisy. Sir Alfred Garrod himself did not conclude that the oxalic acid had existed in the blood, and there was no need for the elaborate discussion of Esbach to show that the occurrence could be otherwise explained. Cantani is said to have found oxalic acid in the blood, but as I have not had access to his original writing I cannot criticise the conditions of the

Further, in spite of one or two opinions to the contrary, the amount of oxalic acid occurring at times as a calcium salt in the urine, if present in the blood in solution, and probably therefore in combination with another base, ought to call forth the serious nervous and other phenomena of oxalic acid poisoning, while the nervous symptoms found in oxaluria are by no means of this nature. Dunlop, indeed, considers them to be identical with those of simple acid dyspepsia. Esbach himself swallowed 6 grammes of oxalic acid, and while it is certain that the whole of this was not absorbed, a considerable amount must have passed into the system, for he found in the urine no less than 0 '181 gramme, the highest determination ever made by the Neubauer method. Yet he says that he experienced no inconvenience from his huge dose, which is surely impossible if so large a quantity of oxalic acid had circulated in the blood in soluble form. A soluble salt of oxalic acid circulating in the blood must of necessity reach the tissues which contain an excess of calcium. Calcium oxalate would be formed and for want of a solvent would remain there permanently. But while this salt has been found in various secretions, it has never been detected in the tissues. Therefore, if oxalic acid is really carried in the blood, it must be in a non-poisonous form, and although we have no direct observations at our disposal concerning the nature of this form, some experi-ments by Heymans 13 have given very suggestive results. Oxalic acid is the simplest compound of its series, consisting merely of two carboxyl groups directly united. Heymans found that as the series is ascended by adding one or more methyl groups so as to form :-

the poisonous properties of oxalic acid are gradually but greatly diminished until the compound finally acts merely as an acid. Thus, on the frog the poisonous dose of oxalic acid being represented by 1 centigramme, for malonic acid it is 2-2.5, for succinic acid 4-5.5, and for pyrotartaric acid 6-6.5. Ascent in the scale of series is very common in metabolism, and may provisionally at least give us an explanation of the state in which oxalic acid is conveyed.

Whatever may be the form which oxalic acid assumes for the purposes of circulation the presence of calcium oxalate in

10 Wi-ner Klinik, vol. xxx., p. 89. In the present paper none but the more important references are mentioned. With the exception of the observation described above, the paper by Toepfer consists entirely of an able review of no less than 376 articles on the subject which have appeared up to 1904 and to which the exact references are given.

11 On Calculous Disease and its Consequences. London. 1856.

the urine is not a mere effect of filtration or diffusion of a pre-existent substance through an animal membrane. Certain observations by Kobert and Küssner 14 have a most important bearing upon this point. They found in experimental poisoning by oxalic acid that crystals of calcium oxalate were seen in the convoluted and straight tubes of the kidneys, where actual secretion takes place, but none in the glomeruli which are concerned chiefly with filtration and diffusion.

It would from these arguments seem probable that the effect of the dyspepsia when present is not to promote absorption of oxalates but to produce one or more substances which so alter the inner metabolism as to provide the kidneys with such material as will produce calcium oxalate.

However distressing to the patient the symptoms which accompany oxaluria may be, they are, nevertheless, not of a serious nature in themselves; but when once existent as a deposit in the urine calcium oxalate is a dangerous body, since its crystals can accumulate to form a calculus either with or without the intervention of a mucous or colloid base as insisted upon by Ord. The stone may consist entirely of calcium oxalate with colouring matter, as, I think, in the patient whose case is to be described, but more commonly the calculus contains a uric acid nucleus, or may even be composed of alternate layers of oxalate and uric acid. The latter feature reminds one of the alternating showers of the two compounds, already mentioned as occurring in simple deposit form, and this point, as will appear, is not without importance in regard to treatment. The shape of the oxalate stone is characteristic—"mulberry shaped," as it is usually called, though "spiked" would be a more correct term. Though generally of small size, it is known to be the most irritating and painful of all calculi, is recognised as the hardest with which the surgeon can have to deal in lithotrity. and has hitherto been considered out of the reach of all solvent methods—which, it must be admitted, have not always been so successful as was hoped, even with more promising materials.

I would maintain that in the following case (which illustrates some of the theoretical points mentioned above) I succeeded in dissolving an oxalate calculus whilst existent in the higher urinary passages of a patient, and with removal of

all the consequent symptoms.

The patient, aged 44 years, was an "insurance explorer," a profession which necessitates, at times, severe mental and physical fatigue. In the spring of 1907 he passed through a period of great overwork, anxiety, and sleeplessness while occupied in settling the insurance claims arising from the West Indian earthquake, and in consequence suffered from what he called "nervous dyspepsia," a diagnosis which was probably more correct than he supposed. On returning to England a year later he placed himself under the care of a physician, who treated his dyspepsia and later discovered a pronounced oxaluria—then, it is said, in the form of a dumb-bell deposit. Subsequent hæmaturia and severe pain in the right flank, extending to the right testicle, made it probable that a calculus had formed in the upper urinary passages of the right side, but several X ray examinations failed to demonstrate this. After consultation with another physician the patient was advised to go to Vichy in the month of August, where during a period of three weeks he took alkaline waters and a diet mostly composed of vegetables. Towards the end of the period he passed a small stone which proved to be composed of oxalate of calcium, but his local symptoms were in no way relieved, his dyspepsia persisted, and his general weakness, ill-health, and loss of weight had increased. He consulted me on Sept. 11th, 1908, on his return to London.

The patient looked ill and worn. He complained of feeling weak, of loss of appetite, and of flatulent dyspepsia. The bowels were irregular, at times constipated, and at times loose. The pulse was of low tension and feeble force. The tongue was coated with a white fur. The stomach and the large intestine were distended with gas, and about three hours after a meal splashing on percussion was detected over the areas of the stomach and cæcum. The patient complained of constant aching pain in the right flank, extending to the region of the sacro-iliac synchondrosis and down the line of the ureter to the right testicle and the inner part of

the right thigh. The slightest movement accentuated the pain, even the act of turning in bed, whilst to walk a hundred yards would cause a "stabbing" pain in the same parts, which made further progress impossible without rest. Micturition was frequent but not painful. The urine passed per diem varied in quantity between 35 and 45 ounces. It was neutral or slightly alkaline in reaction, had a specific gravity of 1015-1020, and on standing threw down a very copious deposit consisting of a little amorphous phosphate, but mostly of small octahedral crystals of calcium oxalate. Even on superficial examination it was evident that the amount of oxalate present could not be caused by mere deposition but must be the result of great over-production.

The urine, even that passed after rest, was reddish in colour, and a red film covered the white deposit; blood reaction was always to be obtained and red blood corpuscles were detected by the microscope. After movement, however, there was pronounced hæmaturia. The urine contained albumin, but at this time it could not be determined if this were due entirely to the hæmaturia, or independent of it. A few ureteral cells and leucocytes were found in the deposit. The right kidney could be palpated and pressed without causing pain, but there was marked tenderness along the course of the ureter, this being accentuated to actual pain at a well-defined spot in the right iliac region. No distension of the pelvis of the kidney could be detected and there was neither pain nor tenderness on the left side. At this stage of the case examination by the bowel gave no evidence of abnormality at the base of the bladder. The patient complained of feeling anxious and worried even when not in pain, and his sleep was short and disturbed, beyond the necessary awakenings caused by frequent micturition. He had general aching and vague pains in the limbs and occasionally in other parts.

A diagnosis was made of (a) oxaluria from excessive production of calcium oxalate, this in turn being the result of disordered metabolism caused by the dyspepsia; and (b) an oxalate of calcium calculus, lodged in the right ureter. symptoms and subsequent course of the case, I think, leave no doubt of the correctness of this diagnosis, even though the stone had not been detected by the X rays. It must be remembered that an oxalate stone is usually small and produces symptoms in severity out of all proportion to its size. It is therefore easily missed by the radiographer, especially if situated low in the ureter, and the one small stone which had already been passed had, indeed, escaped his notice. At our first consultation I hoped that the blood and pain might be caused by scratching of the ureter during the passage of the oxalate stone recently discharged, but the severity and persistence of the symptoms soon negatived this view. Believing that the oxaluria and atonic dyspepsia were due to a state of low vitality and deficient oxidation, I prescribed absolute rest, as nearly as possible in the open air, with a liberal diet of white meat, twice or thrice a week a little champagne, and a medicinal course of dilute nitric acid and strychnine with a tabloid of mixed digestive ferments at the beginning of each meal. An aloes and nux vomica pill each night and a dose of Carlsbad salts once a week were ordered to regulate the bowels.

The symptoms, apart from those of calculus, very soon lessened in severity. The appetite improved, the flatulence after food gradually disappeared, the stomach resumed its normal size, and splashing was no longer to be obtained in the gastric area. The colon still remained distended with gas, and generally, at our consultations, splashing could be elicited over the cæcal area. The large bowel was clearly relaxed, while the stomach had resumed its tone. Almost pari passu with the improvement in digestion, the deposit of calcium oxalate from the urine lessened, until at the end of four weeks, it was comparatively small in amount. At this time the digestion appeared to be normal, and the colon, too, was no longer distended, though constipation persisted. The symptoms of stone, however, were as severe as before, the only difference observable being in the site of the severe pain. This was now deeper in the pelvis, and on rectal pain. examination a distinct resistance could be detected to the right side of the base of the bladder, this spot also being tender. Palpation along the ureter produced only tenderness, where formerly it had caused pain. micturition pain was sometimes felt at the end of the penis, but, usually, as before, the pain radiated into the right testicle and down the inner part of the

Blood in the urine was constant and right thigh. increased, like the pain, by the slightest movement, and a constipated motion also caused pain. I formed the opinion that the stone had slipped a short distance down the ureter and had now lodged near the entrance of the ureter into the bladder, almost in the bladder walls. Copious neutral potations, hot hip-baths, massage along the course of the ureter, and a mixture of belladonna and borax taken by the mouth, all failed to give any relief. The patient, at my request, made several determined attempts to dislodge the stone by sharp walks, bearing the resulting pain as best he could, but this only made matters worse. It seemed that no treatment was available other than removal of the stone by an operation which would probably be severe. The patient, however, wished to avoid this if possible, and yet was desirous of starting on an "exploring" expedition to Mexico early in the present year.

On examining the symptoms of the case it is, I think, obvious that there must have been some chemical connexion between the gastro-intestinal dyspepsia, on the one hand, and the excessive production and deposition of calcium oxalate, on the other, such as that already discussed as being indicated in many cases of oxaluria. With some crude guesses as to the nature of this relationship I wished to make some experiments on the subject, not with any hope of benefiting the patient but merely from medical curiosity. Now, there is no "clinical" or easy method for estimating the oxalates of the urine. Neubauer's method, which I determined to use, is the simplest as it is the oldest, and the numerous improvements which have been made upon it, while increasing its accuracy, have made it more elaborate and removed it more from the use of the practising physician. But even in its original form, with its repeated precipitations and washings and final delicate drying and weighing, some days are required for each estimation, though, of course, several examinations may, with care, be proceeding at the same

I soon found, however, that such determinations as I thought would be necessary to obtain the desired information would require that the analysis of the prine should be made at least twice, possibly six times, for each daynamely, before and after each meal, and not only should the oxalates be estimated, but also the other ingredients of the urine or at least the nitrogenous contents. The composition of each meal also ought to be determined. This is impossible in ordinary practice, nor do I think it could well be done at all, unless two or more persons cooperated in the laboratory work. Probably this is the reason why we are so lacking in precise information as to oxaluria, for I find that observers have hitherto confined themselves to an estimation of the oxalic acid in the 24 hours urine. In the present case, too, the oxaluria and dyspepsia had practically disappeared before I had time to proceed far with such observations as I was able to make, or to devise some easier method of arriving at a result, which I think is quite possible. Knowledge of the chemical connexion referred to is of great importance, and ought to be capable of attainment. I should certainly attempt the solution again, possibly by simpler means, if another occasion should present itself, but so far I have no results worthy of record.

But in making the analysis by the Neubauer method there as to be noted one error of experiment in particular, which, though small, must be allowed for if the result is to be even approximately accurate. The acid phosphate of sodium normally present in the urine holds up a certain quantity of calcium oxalate, when, in the initial procedure, the oxalic acid is precipitated by calcium chloride. It therefore seemed to me feasible that if one could increase the acid phosphate of sodium in the urine by giving large quantities of the salt by the mouth one might possibly at least dissolve off some of the spikes of the oxalate calculus and so facilitate its passage. I put this before the patient as an experiment, and he determined to give it a trial before resorting to an operation. He himself had some knowledge of chemistry, and gave me every assistance in collecting specimens of urine at various times of the day. Dr. Robert Hutchison has already shown that the administration of the salt causes considerable increase in the acidity of the urine, but it was necessary to know whether this was due to the actual presence of the salt in increased amount in the urine. This was ascertained by a trial dose and will be further discussed in speaking of a later analysis. I ordered, at first half an

ounce, then one ounce, and very soon two ounces of acid phosphate of soda to be dissolved in 100 ounces of distilled water and the solution drunk at frequent intervals during the 24 hours, but as far as possible remote from meal times. For half an hour or so after each dose there was considerable uneasiness in the abdomen, mostly from flatulence and a feeling of distension, but a little essence of ginger added to the solution relieved this to some extent, and it was never unbearable considering the end in view. The patient himself tested the acidity of the urine by litmus paper immediately after each micturition and occasionally forwarded me the whole of the urine passed at each micturition throughout the The acidity was increased about half an hour after taking each dose and the small amount of calcium oxalate still being deposited seemed always to be diminished in the urine passed at this time. This observation, however, is, of course, too rough to be of any real value. The oxalate deposit disappeared entirely in about ten days. The blood in the urine gradually diminished and disappeared in about three weeks. The pain lessened gradually, but in six weeks there was no sign or symptom of stone, the patient could walk 10 to 12 miles and take severe gymnastic exercise without the slightest dis-comfort, nothing abnormal could be detected by the rectum, and he felt quite well and in his usual spirits. On deep pressure over the course of the right ureter there was still a little tenderness, and the urine contained a small amount of albumin, some leucocytes, and a few cells of the ureteral epithelium. This state, I thought, was caused by ureteral catarrh, the result of the scratching of epithelium during the passage of the spiked stone. No tube-casts were found and the pulse and heart were normal, thus eliminating kidney disease.

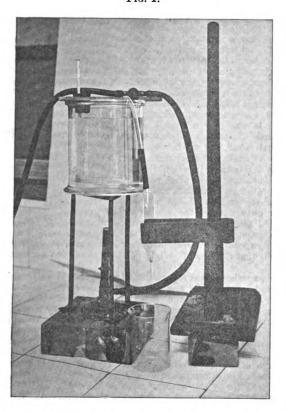

Remedies seemed to have no effect upon the condition, so all treatment was stopped, and the patient resumed his London work. He now presented himself for life insurance, putting his whole case before the company, and was accepted, of course, at a slightly increased premium, seeing that his urine was not quite normal. At the beginning of March he started for Mexico. I had previously taught him how to test the urine for albumin with the magnesiumnitric solution and he has informed me at frequent intervals of his condition. One of his late communications was that he had spent first three and afterwards four hours in the saddle on the same day, most of the time galloping hard over rough ground. He had in no way been reminded of his former trouble, and having tested his urine before and after his ride and also in the interval of rest he had found no albumin. This healthy condition has been confirmed later on several occasions. It seems to me that there can be no doubt that in this case the impacted oxalate calculus was entirely dissolved by the acid phosphate of sodium. No stone was ever passed by the urethra, and I am sure that not the slightest grit could have escaped the attention of so observant a man. The stone, then, must have been entirely composed of calcium oxalate, which is not a very common condition.

This clinical experiment was carried out in the urinary passages themselves and consequently out of sight. As a control it was desirable to repeat it outside the body in vitro under as nearly as possible the same conditions. An apparatus was therefore devised which is represented in the accompanying illustration from a photograph. (See Fig. 1.)

A large receptacle contains fluid which by means of an ordinary mercurial regulator is kept at a constant temperature of 42° C. The fluid is conducted out by a syphon tube drawn out to a point so arranged that between 45 and 50 ounces pass through in the 24 hours, and the fluid on leaving the tube was ascertained to be fairly regularly at a temperature between 38° and 39°C. The end of the syphon tube hangs in a test-tube of which the bottom has been removed and the end drawn out into a funnel whose exit is considerably smaller than the calibre of a ureter. Below this a beaker catches the exuding fluid with its contents. The arrangement thus gives an imitation of the passage of urine through a ureter from the kidney, and the beaker represents the bladder. The stone to be experimented upon should be of such a size as when dropped into the test-tube to lodge at the mouth of the funnel, and therefore larger than any likely to be found in a ureter. Any diminution of volume of the stone will be better gauged by its gradual descent in the funnel than by guessing its size with the unaided eye.

The fluid to be passed over the stone must be an imitation of the urine passed by the patient after taking a 24 hours' dose of the acid sodium phosphate, but it need not contain other ingredients of the urine than the two phosphates of soda, since, so far as we know, none other can influence the solvent action. Indeed, the total urine would certainly decompose during a long experiment and would probably foul the stone, the large receptacle, and the tubes, thus causing an intermission of the flow.

Fig. 1.

To obtain the exact amounts required of the two sodium phosphates, after the patient had recovered and had for some days ceased treatment, I analysed his 24 hours urine for the respective phosphates, and then after giving him for two days one ounce of acid sodium phosphate daily, dissolved as before in 100 ounces of distilled water, I similarly estimated the phosphates of the urine passed on the second day of the administration. Only half his former dose of phosphate was given, for there was reason to think that the former maximum dose was unnecessarily large, and also it was desirable not to exaggerate the amount of salt used in the control experiment. The amount of urine passed on the day in which no phosphate was given was 56 ounces, and after the dose of salt it was 95 ounces, and the half of this would probably pass through each ureter. The two specimens were examined for total acidity, total phosphates, and the amounts of the respective sodium phosphates. The acidity was determined by titration with a decinormal solution of sodium hydroxide, using phenol-phthalein as the indicator, and the acidity was calculated in terms of di-hydrogen sodium phosphate and also of oxalic acid. The total phosphates were determined by uranium nitrate solution, the strength of which was controlled immediately before the experiment by a standard solution of ammonium phosphate, and the amount of phosphates present was calculated in terms of phosphorus pentoxide (P₂O₅). A 10 per cent. solution of barium chloride was then added to the urine to precipitate the mono-hydrogen sodium phosphate and the remaining fluid, which contains the di-hydrogen phosphate, was once more estimated for phosphate. The result subtracted from the total phosphates gives the amount of mono-hydrogen phosphate present in terms of P2O5.

For convenience the results of the analysis are given in tabular form :-

-	First urine 56 ounces.	Second urine 95 ounces.
Total acidity—		1
As di-hydrogen sodium phosphate	0.408%	0.78%
As oxalic acid	0.21 %	0.4%
Total phosphates as P ₂ O ₅	0 095 %	0.3375%
Di-hydrogen sodium phosphate-		
(NaH ₂ PO ₄) as P ₂ O ₅	0.047 %	0.223 %
Mono-hydrogen sodium phosphate-		
(Na ₂ H PO ₄) as P ₂ O ₅	0.048 %	0.1145%
Total amount in 24 hours of—		
NaH ₂ PO ₄	0.79 gramme.	6.35 grammes
Na ₂ H PO ₄	0.8	3.26 ,,

In these figures there are certain points worth attention before proceeding further.

1. The total amount of phosphates passed in 24 hours in the first specimen, which is presumably normal urine and which is estimated at 1·59 grammes (24·5 grains), seems very small when compared with the relative figures given in the text-books, such as 3·5 grammes in terms of P₂O₅ (Neubauer and Vogel) and 48·8 grains as salts (Parkes). I am certain that the older analyses are all vitiated by the fact that a stock solution of uranium nitrate was used for the analysis. Even recent handbooks give no warning against this error. But a solution of uranium nitrate rapidly changes on keeping, losing its power of precipitating phosphates, and unless its strength is controlled immediately before each experiment by a standard solution of ammonium phosphate, as was done in the estimations quoted in the table, the phosphates in the fluid to be tested will surely be over-estimated.

2. As previously pointed out by Dr. Hutchison, the total acidity is greatly increased in spite of the dilution of the urine. In fact, the percentage of acidity is as nearly as possible doubled.

3. The acid sodium phosphate administered by the mouth actually appears as such in the urine.

4. The amount of di-hydrogen phosphates in the urine is only a small proportion of that administered. Doubtless much of the salt passed away by the bowels, but some of the difference is to be explained by the impurity of the drug as now dispensed, as will be presently mentioned.

5. The mono-hydrogen phosphate of the urine is also greatly increased in amount. This is partly accounted for by the increased amount of fluid washing phosphate out of the tissues, but mainly it must be ascribed to a change in passing through the body of di-hydrogen into mono-hydrogen phosphate.

To ascertain the strength of solution required for the experiment, the percentage of phosphorus pentoxide (P_2O_5) found in the analyses must be translated into terms of dihydrogen and mono-hydrogen sodium phosphate respectively, and remembering that the molecule of P_2O_5 will form 2 molecules of each of the salts, we arrive at the composition of the required solution as:—

 $5 \cdot 35$ grammes of anhydrous NaH₂PO₄, $3 \cdot 25$ grammes of anhydrous Na₂HPO₄, with $\frac{95}{2}$ ounces = 1420 c.c. of distilled water.

But in attempting to prepare a solution, containing this proportion of the respective phosphates, a difficulty arose which brought to light a fact important to pharmacists and, indeed, also to those who may prescribe the di-hydrogen sodium phosphate. The amounts as estimated necessarily refer to the theoretically pure and anhydrous salts, while those which are dispensed contain water of crystallisation. It is easy to drive off this water, but the anhydrous salts are very hydroscopic and difficult to manipulate, while in the process of dehydration there is some risk of transforming a portion of the salts into the pyro-phosphate which has a greatly higher molecular weight. One may allow for the water of crystallisation, and there is no difficulty in doing this in the case of the mono-hydrogen phosphate. This is a pharmacopæial preparation and must perforce contain 12 molecules of H₂O. The text-books say that the di-hydrogen

sodium phosphate should have but one such molecule, but it is obvious from the appearance of the salt as supplied by the pharmacists that it must contain a great deal more. I applied to Mr. Caines of Messrs. Squire and Sons for information upon this, and he found that the compound contained 20 per cent. of H₂O and probably more, an amount inconsistent with a pure di-hydrogen phosphate, and on analysis he found in it some mono-hydrogen phosphate with an important amount of sodium sulphate. 13 When given by the mouth this mixture of salts would be separated into its several parts, but clearly the total weight of the compound administered would not represent the amount of dihydrogen sodium phosphate desired for the experimental solution, while the sodium sulphate in so large a dose might cause unpleasant symptoms. The mono-hydrogen sodium phosphate of the Pharmacopæia will serve for our purpose when calculation is made of its 12 molecules of water of crystallisation, but the di-hydrogen phosphate must be prepared in fresh solution by neutralising phosphoric acid with sodium hydroxide according to the formula-

$$NaHO + H_3PO_4 = NaH_2PO_4 + H_2O$$
. It is thereby found that the correct proportions ought to

be obtained by the following procedure: Weigh cut 6.6 grammes of H_3PO_4 Conc. B.P.; add 45 c.c. of $\frac{N}{N}$ NaHO; make up to 100 c.c. with distilled water; dissolve in the liquid 8.2 grammes of Na_2HPO_4 , $12 H_2O$; and make up to 142 c.c. Each volume of this solution diluted with sufficient distilled water to produce 10 volumes ought to give a solution of the same respective strengths of the phosphates

acid sodium phosphate. As a control the experimental solution was analysed in the same way as the original urine and gave: Total acidity = $5 \cdot 3$ grammes NaH₂PO₄; total phosphates = $3 \cdot 337$ grammes P₂O₅; NaH₂PO₄ = $1 \cdot 775$ grammes P₂O₅; Na₂HPO₄ = $1 \cdot 562$ grammes P₂O₅, showing that the solution was as nearly as

as were found in the urine after the administration of the

possible that required.

Mr. P. J. Freyer kindly provided me with an oxalate calculus which he had removed from the bladder, the photograph of which appears below. It was larger than any which could probably be found in a ureter, and after drying weighed 0.442 gramme. This was placed in the apparatus and treated by the phosphate solution for six weeks, the same period during which the patient was under similar treatment. The stone was then obviously smaller, had changed in colour and shape, and had slipped down the funnel into a part much smaller in calibre than a ureter. In the photograph of the apparatus it can be dimly seen. It was of such a size and shape as would be easily passed through the whole of the urinary passages, and possibly even discharged unperceived by an ordinary patient. The solvent process had become very slow in the last few days. After being dried the stone weighed 0.08 gramme. The photographs of the stone before and after the experiment are here given.

Fig. 2.

Calculus before experiment.

Calculus after experiment.

The remnant of the stone was immersed in acetic acid for 24 hours to remove any phosphates, but this caused no apparent change. It was then similarly immersed in hydrochloric acid for the same period to remove any remaining oxalate of calcium, and this process caused the stone to shrink to apparently half the size, and after washing and drying it weighed 0.032 gramme. The more powerful hydrochloric acid solvent is, of course, inadmissible in the

living passages, but I believe that the same great shrinkage would have been effected by a more prolonged action of the phosphate solvent. The remaining portion of the stone was then powdered. A part treated by liquor potassæ dissolved completely. The remainder dissolved in strong nitric acid on heating, and after evaporation gave with liquor ammoniæ the characteristic murexide reaction of uric acid. Clearly, then, we had to do with a uric acid nucleus upon which the oxalate stone had been built.

It remains to prove that the calcium oxalate of the stone had actually been dissolved, for it might be objected that the stone had only been disintegrated by the 1365 ounces of fluid which had passed over it, or that the alkali in the fluid had dissolved a uric acid framework. To detect oxalic acid in so dilute a solution as that which dripped from the test-tube funnel would manifestly be practically impossible. But the answer to the question is given by two observations.

A certain amount of very fine débris, almost dust, had been washed away from the stone. In the patient this would have been passed imperceptibly from the bladder, but in the experiment the whole had collected in the beaker below the funnel, and had been soaked for six weeks in the test solution. It was now collected on a weighed filter paper. It obviously contained the dark-brown colouring matter of the original stone and as it would be difficult to analyse so small a quantity and separate mineral from organic matters, it was determined to weigh it after incinerating to destroy organic matter. The filter paper with residue was therefore incinerated on platinum foil, and the weight of the whole minus the weight of the foil with a similarly incinerated paper gave that of the ash as 0.129 gramme. Doubtless some of this is due to the impurities which would fall into the apparatus from the air of the laboratory during a six weeks' exposure, but even including this source of error it is obvious that the loss of weight of the stone is not accounted for.

The experiment was repeated with a uric acid stone actually removed from a ureter and for which again I am indebted to Mr. Freyer. Before the experiment this weighed 0·32 gramme and it was treated in the apparatus by a similar solution of phosphates, but for this experiment the corresponding salts of potassium were used instead of those of sodium, as being more favourable to the solution of uric acid. At the end of three weeks the stone was paler, but to the eye otherwise unchanged, and it now weighed 0·29 gramme. The difference in weight is no more than could be accounted for by the washing away of colouring matter and it must be assumed that no uric acid was dissolved. Again for convenience the results of the experiments are given in tabular form:—

 Weight of oxalate stone before experiment 0.442 gramme.
 0.442 gramme.

 ,, remnant of oxalate stone after experiment 0.08 ,,
 ,,

 , remnant of oxalate stone after treatment with A and HCl 0.032 ,,
 0.032 ,,

 , débris after incineration 0.129 ,,
 0.32 ,,

 , uric acid stone before experiment 0.32 ,,
 0.32 ,,

 , uric acid stone after experiment 0.29 ,,
 0.32 ,,

Therefore, the thesis is, I think, proved that a calcium oxalate calculus can be dissolved both outside the body and in living urinary passages by acid phosphate of sodium in such a strength of solution as can be produced in the urine of the human subject by the administration per os of an easily supportable dose of the salt. Since in the laboratory experiment successful solution was obtained by such a strength of phosphates as was determined in the urine after the administration of but 1 ounce per diem of acid phosphate, it would seem unnecessary to exceed this amount as a dose, and thus the more disturbing but still bearable effects of 2 ounces, which my patient actually took, may be avoided. It would be desirable that a pure acid phosphate of sodium should if possible be used instead of the mixed compound now dispensed as such. Further, it must be remembered that a calcium oxalate calculus rarely consists of that salt alone, although in all probability it did so in the case described, thus explaining why no residue was passed. The stone used in the laboratory experiment had merely a uric acid nucleus, which when deprived of the surrounding oxalate would have caused no trouble in the urinary passages. But it is well known that stones occasionally consist of alternate layers of oxalate and of uric acid. It is conceivable, therefore, that in attempting to dissolve a stone one might have to alternate the solvent, removing the

¹⁵ I understand that Mr. Caines is now investigating this point and that his results will be communicated to the Pharmaceutical Society.

oxalate by acid phosphate of sodium, and then trying to dissolve the uric acid by giving alkaline potassium salts, as recommended by Sir William Roberts.

Finally, I would recommend that in all cases of prolonged deposition of calcium oxalate in the urine occasional doses of acid phosphate of sodium should be given to dissolve the deposit and so prevent the formation of a calculus. "nervous" dyspepsia were the cause of the condition the phosphate so given would do no harm, but whether, if given continuously, it would influence the production as well as the deposition of oxalate is a matter which is worthy of investigation, but on which I have as yet no information to communicate.

Seymour-street, W.

A CASE OF LATE TRAUMATIC SUBDURAL HÆMORRHAGE; TRAUMATIC LATE APOPLEXY.*

BY A. H. MILLER, M.A., M.B., B.C. CANTAB., M.R.C.P. LOND.

THE term traumatic late apoplexy, first introduced by the late Professor Bollinger of Munich in 1891, has been applied by most writers from abroad, in reference to this subject, to those cases of late traumatic subdural hæmorrhage which are distinguished by the following points: (1) The injury to the head, which, though it may be severe, need not necessarily lead to unconsciousness; (2) the latent period that is to say, the considerable interval of time, occurring before the onset of grave symptoms, during which the patient may continue, more or less, with his usual mode of life till the serious symptoms set in, more or less suddenly, usually ending in death; and (3) the presence of hæmorrhage under the dura mater from a lesion of the brain. Such cases are rare, but they are to be found in the collection of 1/2 cases of traumatic subdural hæmorrhage by Bowen 1 It has been said (Lambert 2) that previous to the year 1891 nothing was known, or rather that there were very feeble ideas on the subject of late cerebral hæmorrhage of traumatic Bollinger,3 in his original paper, endeavoured, origin. by bringing forward 4 cases, to support from a clinical point of view what Duret had found in his experiments on animals. Duret, by means of blows on the head and injections of fluids into the cranium, produced lacerations, traumatic foci of softening in the regions of the lateral ventricles, aqueduct of Sylvius, and fourth ventricle. And he took the view that by blows on the head the lateral ventricles are compressed and the cerebro-spinal fluid is driven from the lateral ventricles into the third and fourth, and at those places which are most narrow the lesions occur, being caused by the rush of the cerebro-spinal fluid.

The necropsy of Bollinger's cases showed essentially, according to him, lesions in the regions such as have just been described. His cases are distinguished by the following features: (1) Though there was an injury to the head, yet consciousness was preserved in all his cases; (2) the patients continued more or less with their ordinary mode of life till the serious symptoms set in; (3) death occurred after the time of the injury as late as, in the first case, 32 days, in the second 12 days, in the third a clear history of trauma is wanting, and in the fourth case 52 days; and (4) the necropsy showed in the first, among the cranial injuries—such as a fine fracture of the left parietal bone and an intermeningeal hæmorrhage-distension of the dura mater with blood, also changes in the ventricular canals, such as dilatation of the fourth ventricle with clotted blood in a thin layer on its walls and capillary hæmorrhages in the medulla. In the second case the necropsy showed distension of the dura mater with hæmorrhage, dilatation of the aqueduct of Sylvius, its walls and those of the fourth ventricle being lacerated. In the fourth ventricle there was a small amount of blood. In the

4 Duret : Études Expérimentales et Cliniques sur les Traumatismes Cérébraux, tome i., Paris, 1878.

third case there was a subdural hæmorrhage. There was also an "apoplectic focus" between the right temporal and occipital lobes, which had broken through into the descending horn of the right lateral ventricle ("Hämatocephalus acutissimus internus"). In the fourth case, besides a broncho-pneumonia at both bases, a cyst of softening in the floor of the fourth ventricle; there was also softening of the left side of the pons with small hæmorrhages in the adjacent

Now when Bollinger published his work it was hailed with delight as not only "bridging the gap" between what had been found by Duret experimentally on animals, and that of concussion in man, but also as furnishing an explanation for those cases where there was some doubt regarding the connexion between death and trauma, the subject for the most part being treated from the medico-legal point of view. Cases were also published as traumatic late apoplexy where it appears that the patient suffered from an ordinary spontaneous cerebral apoplexy, whilst there may or may not have been a definite trauma accompanying it; and again, cases were published as such in which, since the patient recovered, there was no necropsy to confirm the diagnosis. And last year a case was reported as "delayed apoplexy (spaetapoplexie)" which appears to be a case of right hemiplegia with motor aphasia from thrombosis 10 days after being struck on the head (Allen). But in the year 1903 Stadelmann, in an excellent article on "the late diseases of the brain after an injury to the skull," discusses the traumatic softenings of the brain, and he says in reference to brain-soltenings, which are often spontaneous in men who are getting on in years, "many writers are ready to accept this connexion between death and trauma, though many months or even years may lie between the two, and despite the fact of the subjects being already predisposed to tearings of the vessels and hæmorrhage into the brain, from nephritis and arteriosclerosis." And he says, in order to connect with some to brain-softenings, which are often spontaneous in men surety the changes of the brain with the trauma, a great number of restrictions must be complied with. With a view to this limitation he lays down his three conditions regarding these cases of traumatic late apoplexy. "1. The patient concerned must without question have been in good health, no signs of alterations in blood-vessels having existed, syphilis, nephritis, alcohol, and heart disease must have been excluded; also old people who so frequently suffer from arterio-sclerosis cannot be considered; in other words, those who can develop it (apoplexy) spontaneously. 2. The injury must have been considerable, although it does not seem necessary that it should have caused unconsciousness. 3. The symptoms of the vascular or brain lesion must have developed within a short space of time and under our own eyes. If years have intervened in which there has been no medical surveillance, I cannot determine with any kind of precise judgment a relationship between the trauma and the symptoms now appearing. These conditions will be referred to again later.

The next paper of importance was that published by Langerhans in the year 1903. In this monograph, "The Traumatic Late-Apoplexy," Langerhans attempts to demolish the whole of Bollinger's doctrine. As Allen of Philadelphia 9 gives a good and short summary of Langerhans's paper I will quote extracts from Allen's paper. He says :-

This revolutionary work [Langerhans's monograph], a most brilliant critique, might be said to have for its text the following passage which occurs in it: "Because Bollinger is the spiritual father "of the traumatic spätapoplexie, therefore I lay at once the axe to the root of the entire doctrine and set myself in opposition to the generally prevailing

entire doctrine and set myseir in opposition to the generally prevaining opinion."

He [Langerhans] says Allen—first takes issue with Bollinger on account of the title of his paper, "Ein Beitrag zur Lehre von der Gehirnerschütterung." He calls attention to the fact that Bollinger bases his arguments on Duret's experiments, in which, after blows on the head, there were found small punctiform hæmorrhages in the

⁹ Loc. cit.

¹⁰ The term "spiritual father" was applied by Langerhans to Bollinger because he gave his idea to Bohm for an inaugural dissertation in Munich in 1889. The title of this dissertation was Bin Seitener Fall von Traumatischer Apoplexie, I.D. 1889, München. According to Langerhans this case is identical with Bollinger's first case.

aqueduct and immediate vicinity situated just beneath the ependyma, frequently the ependyma being torn. Bollinger thought that he had bridged the gap between these experimental findings of Duret and concussion of the brain. Langerhans says, in the first place, Bollinger's cases failed to show the symptoms of concussion. Moreover, as concussion does not necessarily entail the changes in the aqueduct above mentioned, and as these changes are by no means constant in their connexion with the symptom complex, therefore one must come to the conclusion that these changes are collateral in nature only, and in no sense form the anatomical basis of concussion. For these reasons Langerhans very properly concludes that Bollinger's title is a misstatement.

In dealing with Bollinger's cases Langerhans's criticisms are as follows: In Case I, the fact that there was a considerable fracture of the skull with meningeal hemorrhage makes it extremely doubtful what part, if any, the lesions of the aqueduct played. This is particularly emphasised by the fact that the microsopical examination of the brain no alteration of the blood-vessels, no area of softening, and no traumatic degeneration to account for the hemorrhage. In Case III, the injury must have been 1½ hours before death or else is merely suppositious; there was no alteration of blood-vessels and no area of softening. In Case IV, there was no spätapoplexie and no microscopical examination of the lishmus. There was, however, an area of softening in the lishmus.

in the isthmus.

The utter demolition of Bollinger's views is so complete [continues Allen] that Langerhams's simile, "die Axt an die Wurzel," is well taken. How it has been possible for the medical fraternity, usually so exacting in their demands when anything new is advanced, to accept without question these utterly fallacious lines of reasoning, the glaringly inadequate data; how it has been possible for 12 years to pass before the man [Langerhams] comes forward to fairly riddle the preposterous atructure of pseudo-reason are things which must ever remain wonderful and inexplicable in the history of medicine.

Allen, at the end of his paper, in one of his conclusions, which as he himself says are all based on theory, says: "The cerebro spinal fluid does not play a necessary part in the production of delayed apoplexy, and injury to the region of the aqueduct and fourth ventricle is a collateral circumstance of no etiological moment." Although Langerhans and Allen sought to overthrow the whole of Bollinger's work, yet Professor Oppenheim 11 of Berlin, whose authority on the nervous system is indisputable, in the last edition (1908) of his book on Nerve Diseases speaks in favour of it; he says: "Langerhans opposed very energetically Bollinger's teachings. He does not find these teachings sufficiently supported by what they found, especially the proof is wanting of the softening corresponding to Bollinger's theory in the majority of cases communicated. We still believe that we may adhere to the idea of traumatic late-apoplexy. Most of the papers that have been written on this subject are simply discussions from a medico-legal point of view of the causal connexion between trauma and death, the pathology of the cases from Bollinger's point of view being brushed aside or ignored. Whatever may be the criticisms on Bollinger's paper, yet it, I think, throws light on this

A child, aged 12 years, received an injury to the head on Oct. 9th, 1908, and died 7 weeks and 1 day later from a subdural hæmorrhage as a result of the injury. She was sent to the Salop Infirmary, Shrewsbury, on Nov. 20th, 1908, from the Eye and Ear Hospital, Shrewsbury, on account of a third and fourth nerve paralysis on the right side. With regard to the family history, the patient, except for measles in infancy, had not suffered from any previous disease. She was one of 8 children, 4 boys and 4 girls, who with this exception are all alive and well. Both the father and mother are alive and healthy. There was no history of miscarriages, no evidence of any constitutional disease as syphilis or rickets, and no history of any hæmorrhagic diathesis in the patient or her parents. She was the youngest but one in the family. As to the history of the present illness, on Oct. 9th, 1908, the patient, who was in good health, whilst walking home from school, was alleged to have been struck somewhere over the parietal region on the left side by a stone held in the hand of another little girl of the same This occurred in a childish quarrel. The stone was not thrown, but held in the hand during the act of striking. After being struck the patient did not fall; she cried a little and seemed a little dazed, but she walked home without assistance. There was no bleeding from the nose or ears, and there was apparently no cut on the head. The same evening the patient appeared to be a little drowsy, and wished to lie down on a sofa. The next morning she seemed better, though inclined to be drowsy, but was playful in the For the next fortnight she showed a little irritableness and fretfulness to her parents and she complained of pain in the head. But between the day of the accident and Oct. 16th she attended school for two half days.

On Nov. 20th the patient was admitted to the Salop Infirmary to be under the care of Dr. H. W. Gardner, whose house physician I was at the time. On admission her pulse was 100, her temperature was 98° F., and her respirations were 24. She presented a somewhat wasted appearance, her eyes were a little sunken, and she had a dry scaly skin. was a complete right third nerve paralysis, with ptosis, and pupil widely dilated, not reacting to light or accommodation, and there was also a constant flow of lacrymal fluid, tears running down the cheek and into her nose. The right fourth nerve was also com-pletely paralysed. The only movement of the eye-ball that could be obtained was that of external rota-tion, the sixth nerve being intact. There was no optic neuritis or blurring of the edges of the disc. The left eye was normal in all respects, and there were no paralyses of the other cranial nerves. The knee-jerks were present though obtained with difficulty, especially that on the right. There was no ankle-clonus and the plantar reflexes were flexor on the right and extensor on the left. No anæsthesia was noticed. Motor power of the limbs was good, but there was slight weakness on the right. The mental condition of the child was good. There was no delay in cerebration; she answered all questions readily and easily, but it seemed an effort for her to recollect past events. She did not complain of pain, but when asked she said that her head ached, though the expression on her face was placid. She was very drowsy, lying in bed always on the right side with her head under the clothes. She vomited once—that was on the day of admission. There was nothing abnormal to be noted in the heart, the lungs, or the abdomen, which, though supple, was somewhat sunken. The urine was of specific gravity 1015, acid, and a faint cloud of albumin was present. From this time to Nov. 26th, the day before her death, no noteworthy change was noticed in the patient's condition. The bowels had a slight tendency to constipation. On Nov. 24th the urine was again tested. It was of specific gravity 1030 and acid; no albumin or sugar was present. She took her nourishment well, milk and pudding diet, sitting up in bed to take it. The drowsiness and constant lacrymation continued till the day of her death. On Nov. 26th, whilst at stool, at 5.30 P.M., the patient suddenly cried out, passed her urine under her, and became semi-unconscious and she perspired freely. An hour later her pulse was 60, her respirations 15, her temperature 100°, her left pupil was semi-dilated, and she was able to answer questions. About two hours later she suddenly flexed and straightened both her arms and legs and became completely comatose and very pale. The knee-jerks disappeared and the left pupil became dilated. Later in the evening râles accumulated in the lungs, and she died without recovering consciousness at 6 A.M. on Nov. 27th. The temperature was normal during the time spent in the Salop Infirmary, except on the day of admission, when it rose to 99.20, and again on the day before her death after the first attack of hæmorrhage, when it rose to 100°. The pulse-rate varied between 80 and 90 except during the first apoplectic attack.

Four days after the accident a slight drooping of the right upper evelid was noticed, but not much note was taken of this by the parents till Oct. 26th, when the ptosis having increased, and the child not appearing well, she was taken for the first time to see a medical man. She saw Dr. R. G. C. Thornton of Oakengates, who noted paralysis of the right third nerve, but no sign of any bruising or wound of the head. The patient was then, on Oct. 31st, sent to Mr. C. G. Russ Wood of the Eye and Ear Hospital at Shrewsbury. It was noted on admission that the patient could not open her right eye and the notes state, "Optic discs nil. Total third nerve paralysis." The patient was then put to bed, and for the first week she was very drowsy, sleeping continually, but was readily roused when nourishment was given her. About the end of the first fortnight, that is, Nov. 14th, the patient got much brighter and was allowed to get up. From this date to the 20th, that is, six weeks after the injury, the patient, according to a nurse's statement, seemed quite herself again, playing and romping about with the other children. Since no active eye treatment was necessary the patient was transferred to the Salop Infirmary on the 20th. She walked with a nurse to the latter hospital, a ten minutes' walk, and during the walk the child expressed a wish to see the town.

Brain of the patient (aged 12 years) in the case detailed, showing a cavity from necrosis and softening on the inner and under surface of the right tempore-sphenoidal lobe. The arrow indicates the axis of percussion over the left parietal region.

when it dropped to 60, and just before her death it rose to 160.

A post-mortem examination was performed by the writer about 14 hours later. Rigor mortis was present. The body was that of a well-built child. There were no external marks of any injury on the scalp and there were no signs, on reflecting the scalp, of any old or recent extravasations, and there was no thickening or depression of the bone. When the skull-cap was removed the dura mater bulged all round. On cutting into the dura mater a quantity of dark, tarry blood-clot, limited below by the tentorium cerebelli, issued out. The blood had spread over the cerebral hemispheres on both sides compressing the convolutions. The brain was then removed. It was seen that there was no stripping up of the dura mater from the bone and there was no sign of any fracture, healed or otherwise, at the vertex or base of the skull. The membranes of the brain were smooth and shiny. The brain was without any signs of external injury, except on the under surface of the right temporosphenoidal lobe. On this region there was a small irregular cavity filled with blood. The walls of the cavity, irregular and of a grey colour, were formed by breaking down brain matter. The softening had begun just behind the uncus, extending on the inner side to the inner edge of the temporo-sphenoidal lobe and externally as far as the temporo-occipital sulcus. Posteriorly, it reached to about the level of the anterior third of the pons. The measurement of the cavity was 22 millimetres long, 3 millimetres broad, and 9 millimetres deep. Adherent to and on the under surface of the pia mater, at the posterior margin of the cavity, was a portion, of the size of an almond, of an ante-mortem blood-clot. There was also blood-clot on the inner side of the cavity involving the right third and fourth nerves. The subarachnoid space in the middle line was also filled with clotted blood which had burst through the arachnoid membrane in the region of the optic chiasma to spread over the whole of the cerebral hemispheres. The whole brain was then put into 10 per cent. formalin. When hardened, it was cut with a knife into a series of transverse sections, 14 in all; the cerebellum and fourth ventricle were divided antero-posteriorly. To the naked eye the softening process on the floor of the cavity was extending downwards into the white matter for about three-quarters of an inch. In this region the brain was softer and presented little grey spots of softening. The softening process was confined solely to the region of the No patches of softening, lacerations, or hæmorrhagic foci were seen in any of the ventricles, aqueduct of Sylvius, pons, or medulla, and the ventricular canals were not in the least dilated. Except for the cavity on the under surface of the right temporo-sphenoidal lobe the brain appeared to be normal. (See Fig. 3.)

The remainder of the post mortem showed nothing abnormal. The heart was healthy and there was no endocarditis. The lungs were somewhat cedematous at their bases. The kidneys were healthy, the capsules stripping easily. Paraffin sections of a portion of one of the walls of the cavity stained with hæmatoxylin and Van Giessen showed the following. Between the subarachnoid and the pia mater, where the blood-vessels running into the brain are situated, there was a considerable amount of blood. There were several vessels to be seen in this region. In some small vessels there was thrombosis, with lamination of the clot, and leucocytosis in the centre of the clot, probably indicating injury to the wall of the vessel. In another small vessel was a hyaline clot with a moderate degree of leucocytosis in the perivascular spaces surrounding it. In the cerebral tissue, just below the pia mater, was a large hæmorrhage into the substance of the brain which was compressed and necrotic, and adjacent to this, and running deeper down into the white matter, were small extravasations in the brain matter running in lines, and parallel to each other. There was a considerable amount of granular débris and degenerated and pigment cells. A search was made for bacteria by appropriate stains and by clearing the sections of the débris by passing them through absolute alcohol, ether, acetic acid, and warm KOH, but none were seen. There were no miliary aneurysms, and the walls of the large arteries at the base of the brain showed nothing abnormal, and there were no signs of any new growth either of the neuroglia or of the meninges.

This case is a valuable one in that it fulfils all the points which have been laid down with regard to these cases—viz., the

injury, which was definite, the latent period, and the interval of time between death and trauma—and it also fulfils all the conditions laid down by Stadelmann. But in this case lesions in relation to the ventricular canals were conspicuous by their absence. But there were softening and necrosis on the under surface of the temporo-sphenoidal lobe on the side opposite to that of the injury. And just as I believe Bollinger is right in the main, in ascribing the lesions in his cases to the agency of the cerebro-spinal fluid, so the lesion in this case can be ascribed to the same agency; and that this is a true case of traumatic late apoplexy in the sense of Bollinger's teachings. The proof of these statements is as follows. If the lesion in this case had been produced by contrecoup, which is described by some as taking place by the jarring of the brain on the opposite side of the bony skull, the softening and necrosis ought to have been on the external surface of the right temporo-sphenoidal lobe, but the lesion is on the inner side of the lobe. Nor was the injury on the same side of the brain as the trauma, where the left temporo-sphenoidal lobe lies in contact with the body of the sphenoid bone, for this is the part of the brain that ought to have been damaged if such an explanation be sought. Again, in this child's skull, at the base, there were no elevations of the great wing of the sphenoid, no spicules of bone, &c., projecting into the brain, but the surface covered with dura mater was quite smooth.

Now Duret 12 (see Figs. 1 and 2) by his experiments on animals formed the law: "The lesions produced by concussion occupy principally the spaces where the cerebro-spinal fluid circulates." Miles 13 of Edinburgh in 1891 followed up and practically confirmed Duret's remarkable work on concussion. At the base of the brain are the large subarachnoid spaces filled with cerebro-spinal fluid. One of the largest is the cisterna basalis, formed by the arachnoid membrane stretching across the projecting temporal lobes. Within it is the circle of Willis. From the diagrams it can be seen that the lesion on the child's brain is at the side of this sac, and that it is exactly in the line of the axis of percussion of the blow over the left parietal region. I can well imagine the wave of cerebro-spinal fluid, under the influence of the blow, distending the cisterna basalis and spreading over the inner and under surface of the right temporosphenoidal lobe and repturing the small vessels suspended in the cerebro-spinal fluid in the meshwork between the arachnoid and pia mater. 11 What the exact pathology of the softening and necrosis is, it is not easy to say. Bollinger explained his as follows. First the trauma to the head, then "traumatic degeneration," which led to "softening necrosis," to "alterations" of the vessels in consequence of the softening, and finally to the fatal apoplexy due to the altered resistance and raising of the arterial pressure.

In this case I think the lesion may be explained as follows. We know from Miles's experiments that rupture of the small vessels takes place by the wave of cerebro-spinal fluid. And it was probably this hæmorrhage which caused the ptosis to appear on the fourth day after injury. The small vessels,15 then, running into the cortex being end-arteries and therefore not anastomosing freely, being ruptured and probably thrombosed as well, together with venous thrombosis of the small vessels, cut off the nutritive supply to that area of the brain as shown by the lesion. Necrosis and softening took place in consequence of loss of nutrition to the brain substance till the external resistance to the vessels was greatly diminished. The straining at stool (in this patient),

¹³ Miles: On the Mechanism of Brain Injuries; On the Effects of Blows Over Different Parts of the Cranium, Laboratory Reports of the Royal College of Physicians of Edinburgh, vol. iv., 1892.

14 It must be remembered that each blood-vessel as it enters the brain substance has two distinct lymph spaces. (1) the adventitial lymph space of Robin between the tunica muscularis and tunica adventitia and continuous with the subarachnoid space; (2) the perivascular lymph spaces, the latter of which continues to surround the blood-vessel on to its minutest ramifications, are filled with cerebro-spinal fluid in which the blood-vessels are suspended. (Miles.)

13 With regard to the lamination of the clot in the interior of a small vessel, Professor Woodhead tells me that such lamination may result from an injury to the vessel wall itself or to damage of the vasa-vasorum of the vessel. The vasa vasorum would be very liable to rupture by any change in their external resistance such as would occur from a rush of cerebro-spinal fluid from one space into another. And rupturing of the vasa-vasorum would affect the nutrition of the vessel wall, including the intima, comparatively slowly, the clot being laid down in layers, and this would help to a count for the length of time which existed between the trauma and death.

increasing the blood pressure, caused rupture and the fatal There were probably two attacks of hæmorrhage the first in which the child was rendered semi-unconscious, and the second about two hours later causing the absolute coma and death.

Bollinger brought forward his four cases to support, from the clinical point of view, Duret's cerebro-spinal fluid theory of concussion, yet he limited his cases only to those where the lesions occurred round the ventricular canals, pons, and To my mind, he did not go far enough; he omitted to collect, or to make mention of, cases of late traumatic subdural hæmorrhage where the lesions are in relation to the spaces on the surface of the brain. And from what I can make out from reading reports of other cases published since then by others, the interest in the description of the case has always been devoted to the ventricular canals, whilst the mentioning of the relationship to the other spaces has been neglected; but I am quite open to correction in this. Michel 16 reported a case of traumatic late apoplexy where, from a blow received on the vertex anteriorly, the occipital lobes, undergoing softening and necrosis, ruptured into the lateral ventricles. Here we have the posterior extremities of the occipital lobes bathed by the superior cerebellar lake. Not only with the late but in the recent hæmorrhages we see the same thing. For instance, in a case reported by Miles 17 a patient, aged 22 years, had a blow on the occiput from falling backwards downstairs on Nov. 30th, 1889, and died on the same day. Necropsy showed "abrasion just under external occipital protuberance, in middle line; another over right parietal eminence. Skull.-No fracture of vault or Brain.—Left hemisphere very extensive clot all over convex aspect of this hemisphere, and extending on to under aspect of frontal lobe. Especially thick in region of fissure of Rolando, middle parts of ascending frontal and parietal regions being markedly compressed. Over Broca's convolution was a large contusion with extravasation into brain substance, and this extended on to middle temporo-sphenoidal convolution. On under aspect of temporosphenoidal lobe of this side was a contusion with extravasation of blood. Right hemisphere: but for engorgement of vessels of this hemisphere there was nothing abnormal.

From the diagrams of the subarachnoid spaces, both on the base and on the sides of the brain, the lesions of the brain, in Miles's case, are all in the neighbourhood of these spaces. These cases are, I think, sufficient to show that from Miles's work, as also in so many cases of head injuries-and this especially applies to where the lesions are "contre-coup," regardless of whether the symptoms come on early or late—the lesions of the brain which are present bear a distinct relationship to the subarachnoid spaces both on the base and on the sides of the brain along the course of the Sylvian and Rolandic fissures. The difference between an early or late termination of the affection depends upon such factors as the site and severity of the blow, the parts of the brain injured, and the general condition of the patient as regards other concomitant pathological processes. But why softening and necrosis leading to hæmorrhage should occur in one case and not in another I must leave to others to explain. Stadelmann applied his conditions to those who wished to connect a lesion of the brain with a trauma received some time before. His remarks have generally been added by writers on this subject of traumatic late apoplexy. But it seems to me a little artificial to hedge these cases round with so many restrictions, for I do not see why, as in Michel's case, 18 a patient with arterio-sclerosis should not come under the laws of concussion the same as a healthy person, though I suppose in some cases it is difficult to exclude a spontaneous cerebral hæmorrhage. For those who are interested in this, Kurt Mendel 10 goes into the subject fully.

In conclusion, I wish to express my thanks to Dr. Gardner, Mr. Russ Wood of Shrewsbury, and to Dr. Thornton of

Oakengates for permission to publish this case and for the use of their notes, and especially to Professor Sims Woodhead for his kindness for his suggestions for the making and in the interpretation of the sections of my case. Cambridge.

STARCH DIGESTION IN BABIES.

BY EDMUND CAUTLEY, M.D. CANTAB., F.R.C.P.LOND., PHYSICIAN TO THE BELGRAVE HOSPITAL FOR CHILDREN AND THE METROPOLITAN HOSPITAL.

It is frequently argued that because there is no starch in human milk all starch-containing foods are contra-indicated in the feeding of infants during the first few months of life. In support of this various observations on the presence or absence of a diastasic ferment in the saliva and in extracts of the salivary glands or pancreas are constantly quoted. Most of these possess almost the hoariness of antiquity, and the time has certainly arrived when we should reconsider the position. On the one hand we find physicians maintaining that no starchy food is permissible for an infant under six months of age. On the other we have the widely distributed practical experience that barley water can be used as a diluent of cows' milk during the first few days of life, as well as subsequently, without damage to the child and often with decidedly beneficial results. Probably the truth lies midway between two extremes and, as I hope to show in this paper, small quantities of starch can be given to infants and can be adequately digested and assimilated. Not much stress can be laid on the absence of starch in human milk, for when a baby is artificially fed it is put on a diet which in many respects differs from human milk, although it may contain identical percentages of the chief constituents, protein, fat, and sugar, and possess the same calorie value. It can no longer be maintained, for instance, that the caseinogen is identical in the two fluids; nor that any scheme of dilution or laboratory modification of cows' milk will render it identical with human milk. The percentage system of feeding has been tried in the balance and found wanting. It is not essential that the carbohydrate in infant feeding should be lactose. Cane sugar is often used and there is much in favour of starch in preference to this form of carbohydrate. Similarly I hope to show that our ideas on the subject of starch in infant feeding require modification and that, with proper limitation in the quantities given and the form in which it is prescribed, it is more valuable as an article of diet and a more rational diluent of cows' milk than water, gelatine solution, and such-like fluids.

The amylolytic ferment is secreted in the saliva during the early months of life. Schiffer (1872) gave infants starch paste in bags to suck for five minutes. One infant was a few minutes old and the other two were under three hours. Chemical tests showed that sugar was produced from the starch. In infants of 16 days and 3 months the change was more active. Korowin (1873) found that the juice of the parotid in the first days of life readily converted starch into sugar. Zweifel (1874) made extracts from the parotid and found that it contained an active amylolytic ferment, even before birth. Extracts of the submaxillary glands had no such action. Recently Ibrahim (1909) found the ferment in both the submaxillary and parotid glands of 22 premature and 12 new-born infants. Schilling also found the ferment in the submaxillary glands. These observations are sufficiently definite to justify the assertion that the saliva of infants at birth contains an amylolytic ferment, and that it gradually increases in activity as the infant gets older. It must not be forgotten, however, that salivary secretion is scanty in young infants and rarely appreciable before the age of two months. About 1 cubic centimetre is secreted in 20 minutes at the end of the first month of life, but at the end of the third month a similar quantity is secreted in two minutes. The activity of the ferment is not confined to the short time that the food remains in the mouth, but continues in the stomach until stopped by the acidity of the gastric juice. Compared with the action of pancreatic secretion the importance of the saliva is relatively small in early life.

The meconium contains the diastasic ferment; so, too, the stools of early infancy; one part converts one-twentieth of starch into maltose. Jacobi states that the diastasic power

of the pancreas begins in the fourth week of life and remains very feeble up to the end of the first year. He found that infusions of pancreas of infants who had lived three weeks produced no change in starch. Zweifel and Korowin found the ferment absent under the age of three weeks. Korowin states that it is not until the end of the third month of life that this secretion has any appreciable action on starch. More recently Ibrahim (1909) has found the amylolytic ferment in the pancreas of the premature and the new-born. Moro found it present in seven infants, two of whom had died at birth; Gillet and Jakubowisch have also found a diastasic ferment in the pancreas of the newly born; weak at first, but becoming rapidly more active. Reichert and Flint have brought forward evidence that another ferment capable of inverting starch is secreted by the epithelial cells of the buccal and intestinal mucosa. Heat and moisture will invert small quantities of starch without the aid of a ferment.

Experimental observations on the quantity of unchanged starch in the fæces of infants taking starch in the food have been carried out by Heubner and by Carstens on infants under two months of age, and have shown that considerable quantities of the starch were absorbed, the amount varying in different infants. Friedlander (1909) states that by a modification of Einhorn's bead test he has been able to demonstrate that newly born infants can digest starch perfectly. He used cooked flour for the test. Kerley examined the stools of 87 children under one year of age. Of 60 cases, carefully studied, starch digestion was poor or indifferent in 19 and good in 41, of which 11 were under six months of age.

Clinical experience also supports the view that weak starchy fluids can be digested and are advantageous as diluents. Jacobi has always advocated barley or oatmeal water as a diluent of milk, even in the first few weeks of life. Milk and barley water is a practically universal diet in this country for artificially fed infants. For many years I have made use of it after the second month of life in the diet of hospital out-patients with apparent benefit, though occasionally water has been found preferable. Test-tube experiments to estimate the effect of heat and attenuants on the curdling of cows' milk with acetic acid, carried out some years ago, showed that the finest curds were obtained when thin barley water was used as a diluent, and that they were finer than with plain water. There was no marked difference in the reaction to rennet in favour of barley water as a diluent. Starch is used for two purposes in infant feeding-viz., for nutrition and in order to render the curd produced in the stomach finer. As regards the latter action it has a definite effect on curdling by acid and very little on curdling by rennet. Its value in nutrition depends upon the degree of conversion of which it is capable in the alimentary tract of infants, and this depends greatly upon the form in which it is presented. A large number of physicians advocate its use even in very young infants, shortly after the second or third month of life, very often from birth. Finkelstein claims that it can be used with advantage after the second or third

The conversion of starch in the alimentary tract is not the simple process one might be tempted to conclude from the above observations. Other ferments are present which may affect its digestion, or secretion is directly influenced by a ferment which increases the activity of the pancreas. Martin and Williams (1889) showed that the bile is an auxiliary to the amylolytic action of the pancreas, possibly due to the bile salts. Pawlow and others have found in the intestinal juice a special ferment, enterokinase, which stimulates the activity of the pancreatic ferments. Apparently the pancreas, and probably also the salivary glands, can adapt their functions to the nature of the food supplied. F. A. Bainbridge (1904) published some interesting observations on the ferment lactase which inverts milk sugar into galactose and dextrose preparatory to absorption. This ferment was found by Ibrahim (1909) in the intestinal mucosa of new-born infants. Bainbridge found it present in puppies while suckling and absent in adult dogs. He did not find it in the pancreas of a new-born child, nor in those of puppies taken away from the mother and killed almost immediately after birth, but it was present in the intestinal mucosa of the puppies. Apparently the lactase is not present in the pancreas at birth, but quickly appears if milk is given. On feeding adult dogs with milk Bainbridge was able to produce the secretion of lactase

by the pancreas. This is conclusive evidence that the nature of the pancreatic secretion is adapted to the diet. Walther proved this in connexion with starch. On a diet containing equal amounts of nitrogen, one consisting of 600 cubic centimetres of milk and no starch and the other of 250 grammes of bread, the number of units of amylolytic ferment secreted was 342 for the milk meal and 1601 for the bread. It was also found that if the new diet was maintained the ferment action of the pancreatic juice became daily more and more adapted to the requirements of the food. In a prolonged experiment the pancreas was first trained to secrete a strong proteolytic juice, and its protein-digesting power was gradually reduced to nil by changing the diet from flesh to one of milk and bread. At the same time, the amylolytic ferment was increased. Pawlow states that in the same animal the ferment activity could be varied and reversed by changes in the diet.

The nature of the starch affects its value as a food, for some varieties are acted on more rapidly than others by diastasic ferments. Solera found that potato starch was changed most rapidly, and then wheat, maize, and rice starch in the order named. Malay also found that potato paste and then oat and wheat starch were the most rapidly changed. Starch is digested with difficulty unless it is previously converted by heat into "soluble starch," as in making barley water. If starch grains are mixed with hot water the granulose swells up and bursts the cellulose envelope of the grains and forms a sticky mass or starch paste. On boiling it becomes gradually thinner and forms "soluble starch, intermediate stage in the conversion of starch into dextrins and sugar. This conversion is quickly brought about by diastasic ferments. It is easy, therefore, to understand that barley water, as commonly prepared, is a cereal decoction readily capable of digestion by the infant. The perreadily capable of digestion by the initial. The percentage of starch in barley water varies with the process of preparation. Corlette (1905) found that the average percentage of starch was 2.03 in barley water prepared as follows: "Take two heaped teaspoonfuls (= 18 grammes) of pearl barley, wash it and put it in a pint of cold water; then put it on the fire and simmer till the whole is reduced to only two-thirds of a pint. This is then strained and the liquid part constitutes barley water." Maynard Ladd added This was cooked for 30 minutes and again made up to two pints. The resulting barley water contained 3.5 per cent. of starch. Holt gives the percentage of starch in barley water as 1.63. The barley water was made by adding two tablespoonfuls of barley to one quart of water and boiled continuously for six hours, keeping the quantity up to the quart by the addition of water, finally straining through fine muslin. These analyses suggest that the evil effects of starch in the food in early life are due to quantity and mode of administration, rather than to starch per se, for it has been shown that most infants can digest ordinary barley water.

Artificially-fed children are particularly prone to gastro-intestinal disturbance, whether fed on modified milk alone or with some form of starchy diluent. They are even more liable to such disturbance when the starchy preparation is increased at the expense of the milk. A starchy diet without a due supply of milk is deficient in protein, fat, and salts. So it is easy to understand that if a child is fed on thin arrowroot gruel, cornflour, or such like foods, and milk more or less omitted, it is certain to be ill quite as much from the absence of various necessary constituents as from the excess of starch. Even under such conditions as this I have known a baby remain apparently well for six months although fed entirely on thin oatmeal gruel, proving conclusively that in that particular instance there was no such thing as starch poisoning. A study of the Calorie value of foods shows that a diet of arrowroot gruel contains only about a third to a fourth of the number of Calories present in a similar quantity of human milk.

There is positive evidence that starchy food is distinctly beneficial during early life. In the treatment of acute gastro-intestinal disorders it is common practice to stop all milk and put the child entirely on a diet of barley water or rice water. Cereal decoctions are unsuitable culture media for the growth of the proteolytic bacteria on which so many cases of infantile cholera depend. Indirectly the starchy diet acts as an intestinal antiseptic. There is evidence that it is of value as a direct antiseptic, for it aids in the production of lactic acid. The treatment of gastro-intestinal

disorders by buttermilk feeding and by the lacto-bacilline treatment shows that the diet is much more effective when some starch or sugar is added to the diet.

The general conclusions from the above observations afford physiological and chemical support of the empirical use of starch in infant feeding and may be summed up shortly as follows: 1. A diastasic ferment is secreted by the salivary glands and pancreas of new-born infants and even before birth. 2. Its amount and activity are slight in the first few weeks of life and after that rapidly increase. 3. The glands, notably the pancreas, can be trained by means of a starchy diet to the secretion of an increased amount of the amylolytic ferment. There is no inherent reason why this training should not be begun shortly after birth in the case of the bottle-fed infants instead of waiting until the child has attained the age of six months, as so commonly advised on purely theoretical grounds. 4. Practical experience has shown that the usual barley water contains about 2 per cent. of starch. If mixed with an equal quantity of milk there will only be 1 per cent. of starch in the mixture. Such an amount is non-injurious and almost certainly is beneficial, for it encourages the growth of lactic acid bacilli and the formation of lactic acid. These organisms are of undoubted advantage in the prevention of the growth of proteolytic 5. If a starchy food is used in the first few weeks of life it is advisable to begin with a milk mixture which will not contain more than 0.5 per cent. of starch and to gradually increase the amount as the child gets older. Indeed, at any age when a starchy food is first given it should be in very weak solution and slowly strengthened up to as much as 3 to 5 per cent. If the stools become very acid, or if they give a distinct starch reaction, the percentage of starch in the diet must be reduced. 6. Special care must be paid to these considerations in the first two months of life because of the deficiency of salivary secretion. Further investigations may possibly show that this is a point of little importance as the pancreatic secretion may be sufficient in quantity and activity. 7. The evil effects of starch in early life are due to (a) excess; (b) its administration in the form of a more or less insoluble emulsion instead of as soluble starch; and (c) the substitution of starch for the necessary protein, fat, and salts. In other words, the mischief results from deficiency of necessary proximate principles of diet rather than from the presence of starch.

Upper Brook-street, W.

LUNG PUNCTURE: A NEW APPLICATION OF CLINICAL PATHOLOGY.

BY THOMAS J. HORDER, M.D. LOND., F.R.C.P. LOND., PHYSICIAN TO THE GREAT NORTHERN CENTRAL HOSPITAL; MEDICAL REGISTRAR TO ST. BARTHOLOMEW'S HOSPITAL

I .- General.

PUNCTURE of the pleura has long been practised as PUNCTURE of the pieura has long been practised as a valuable aid to diagnosis. For many years before the birth of bacteriology the procedure yielded important knowledge. But prior to the advent of the bacteriologist a "dry" puncture of the chest wall was wholly negative in its information. The needle either entered a pleural effusion or it entered the lung. If the latter, the very small amount of blood-stained fluid which was because the away by the swringe was neglected. And even brought away by the syringe was neglected. And even to-day it is the rule for this valuable material to be put aside without examination. As a matter of fact, these few drops of lung juice may yield very important positive information as to the presence of disease within the lung itself and also as to the nature of such disease. During the past four or five years I have every now and again employed this method of investigation with extremely useful and interesting results. As I can find no reference to such an application of clinical pathology I have thought it well to collect such observations as I have been able to make with regard to it.

In actual practice a diagnostic puncture of the lung may be made under two conditions: (1) a pleural effusion is suspected and the result of the puncture negatives this; or (2) no fluid is suspected in the pleural sac, but the lung is deliberately punctured for the express purpose of discovering material obtained is no less valuable in the first than in the second of these two conditions.

II. — Indications.

The indications for lung puncture will vary somewhat with the desire of the physician for accurate knowledge with regard to the condition of the patient. In brief, it may be said that the puncture is indicated: 1. In any case yielding signs of consolidation of the lung, in which careful examination of the sputum fails to reveal the nature of the disease. It is, perhaps, pushing the value of "ocular demonstration" rather far to say that lung puncture is indicated in a straightforward case of lobar pneumonia, even when there is no sputum for examination. But it should certainly be undertaken in any such case if the desired clinical course is departed from in any way to the prejudice of the patient. The puncture will frequently reveal the existence of a mixed infection (e.g., B. influenza and pneu-mococous) when this is not suspected. Two other indications 2. In abscess it is useful to obtain a specimen of pus from the actual seat of suppuration, for thereby a knowledge of the causal microbe is gained, often a matter of great difficulty or impossibility when dealing with the sputum. 3. In bronchiectases the same comment holds; the flora of the sputum is notoriously varied and difficult of interpretation.

III .- Technique.

The mode of performing the puncture follows exactly that of exploration of the pleura. For obvious reasons it is advisable to use a good-sized needle. Provided this be quite clean and sharp the patient suffers very little discomfort. And if due regard be had to the anatomy of the heart, big vessels, and diaphragm no damage is at all likely to occur. The syringe, of course, has been recently boiled and contains no disinfectant. The puncture is made at a point on the surface of the chest immediately over an area of lung yielding abnormal physical signs. The needle is inserted into the lung, the piston is withdrawn about an inch so as to keep up a gentle suction, and the needle is then slowly removed whilst the skin is supported by the finger and thumb of the left hand. As the needle leaves the chest wall two or three drops of bloody fluid are seen to spurt from it into the barrel of the syringe.

The method of dealing with the material depends somewhat upon the amount obtained. Sometimes the amount is so small that it is advisable to utilise the whole of it for purposes of cultivation of micro-organisms, the method resolving itself into one of "lung culture." If, however, the quantity admits of this, or if a cytological, rather than a bacteriological, examination is suggested from the nature of the patient's illness, films are also prepared from the material and stained as in the case of pus. In either case the needle is inserted into a little sterile salt solution, just sufficient of which is drawn up into the barrel to mix with the lung juice, and to enable this to be completely discharged. If a bacteriological examination only be decided upon the diluting fluid may well be a little sterile broth from a culture tube. The mixture of lung juice and diluting fluid is now squirted out, partly on a glass slide for film examination and partly on to the surface of an agar slope, which is incubated at 37.5°C. As the material removed from the lung is almost certain to contain a little blood, even hæmophilous microbes, such as B. influenzæ, need no other medium than ordinary agar.

IV. - Illustrative cases.

The following cases demonstrate the assistance in diagnosis and treatment afforded by lung puncture.

CASE 1. Abscess of lung following perforated duedenal ulcer.—The patient was an International football player, under the care of Mr. C. M. Hewer of Tarporley, who diagnosed perforation of a duodenal ulcer. The perforation was sutured by Mr. G. P. Newbolt of Liverpool. A week after the operation signs of pleurisy developed at the base of the right lung, with fever and severe illness. Percussion dulness followed at the seat of the pleurisy, but exploration of the pleura by needles was negative. When I saw the patient with Mr. Hewer there were marked signs of consolidation of the lung, high intermitting fever with sweats, and dilated heart. The condition of the abdomen was satisfactory. Four separate punctures with a good-sized needle failed to show fluid in the pleura. The lung juice obtained the nature of a disease process within the lung itself. The at the last puncture, however, was dealt with as above

described, and on the next morning there was seen to be a copious and pure growth of streptococcus on the agar slope. On further examination the streptococcus was found to be S. fecalis. Polyvalent anti-streptococcus serum was given liberally and undoubted benefit resulted. The consolidated lung then underwent liquefaction, and large quantities of very feetid pus were expectorated, as much as 1½ pints in the day. But the acute and alarming symptoms had passed off. Vigorous treatment in the open air, with respiratory antiseptics by the mouth and by inhalation, led to complete recovery.\(^1\) In this case the lung puncture was not performed deliberately but during the search for an empyema. But the important information obtained from the examination of the lung juice in this instance, proving as it did the presence of a pulmonary focus of infection by streptococci derived from the bowel, led me to employ the method directly in other cases where there was doubt as to the nature of the disease in the lung.

CASE 2. Abscess of lung following incomplete abortion. - A woman, aged 30 years, came under observation 14 days after a miscarriage, suffering from fever, rigors, anæmia, and shortness of breath. The uterus was curetted and treated with antiseptics without improvement. A week later signs of consolidation appeared at the base of the right lung in front. with local pain and cough. There was no sputum. Exploratory puncture of the lung drew off two or three drops of bloodstained pus, and these yielded a pure culture of Staphylo-The signs persisted and the patient grew oocous aureus. worse. An operation was advised, but it was considered that the indications for resection of a rib and exploration of the lung were insufficient. Death occurred a week after the puncture was made. Post-mortem examination showed an abscess situated in the right lower lobe of the lung close to the pleura. The pus from the abscess gave a pure culture of S. aureus.

CASE 3.—Appendioectomy; general peritonitis; pneumonia.—A child, aged 5 years, was admitted to the Great Northern Central Hospital under the care of Mr. E. C. Stabb. Laparotomy revealed a gangrenous appendix, which was removed. The child did very well until the tenth day, when signs of peritonitis and pneumonia appeared. Puncture of the lung was undertaken, and a few drops of bloody fluid were obtained which gave a copious growth of pneumococci, B. ooli, and B. influenza. The proof of the mixed infection of the lung was very striking. A dose of pneumococcus vaccine was given, but the child was obviously in a desperate condition at the time and died four days later.

Case 4. Mycosis fungoides; streptococcal and staphylococcal infection of the skin; extensive pneumonia.—A man, aged 38 years, who had suffered for several years from recurring attacks of mycosis fungoides, came under observation with a large axillary abscess due to staphylococcus infection. There were also present several superficial foci of streptococcal infection on the chest and limbs. The abscess was incised, scraped, and drained. A spreading pneumonia developed, but whether this was streptococcal or staphylococcal in origin was uncertain. Lung puncture gave a little blood-stained fluid which both in films and on culture showed abundance of Staphylococcus aureus. Two small doses of the killed staphylococcus were given as vaccine, but the condition proved to be the usual mode of termination of this uncommon skin disease.

Case 5. Erysipelas; bronchepneumonia.—An infant, aged 7 months, was admitted to the Great Northern Central Hospital under my care, suffering from extensive erysipelas of the scalp. Several small superficial abscesses developed, and from these a pure culture of Streptococous pycgenes was obtained. The condition improved under treatment by antistreptococcus serum. There developed later several vesicles on the scalp, and from these a growth of S. aureus was obtained. Patches of consolidation also appeared in the lower lobe of the right lung. Puncture of one of these areas revealed a pure staphylococcal infection. The infant was accordingly vaccinated, but without good effect.

CASE 6. Delayed resolution in pneumonia; negative lung punoture.—A young man, aged 20 years, was admitted to the Great Northern Central Hospital under my care on the second day of his illness, suffering from pneumonia, with consolidation of the right lower lobe and some associated bronchitis.

A pseudo-crisis occurred on the seventh day, but the temperature rose again on the same day, and the signs of consolidation remained unchanged. On the twenty-third day the temperature was still raised, in an intermittent fashion, and the physical signs, as well as a skiagram, showed the lung to be still hepatised. The leucocyte count was 20,000. Examination of the sputum showed no tubercle bacilli. The solid lung was punctured, and the blood-stained fluid was submitted to culture. The agar tubes remained sterile. By the twenty-sixth day the temperature was normal and the general condition was excellent. Injections of fibrolysin were given; the patient left the hospital in good health but with the lung still solid.

V. - Concinsion.

Altogether I have punctured the lung for diagnostic purposes in some 14 cases. Those above cited serve to show the kind of information that can be elicited by this mode of examination. It may possibly be found of service in suspected cases of acute pulmonary tuberculosis, in which condition sputum is so commonly absent. In one such case I punctured the affected lung, but failed to demonstrate the tubercle bacillus in films prepared from the material obtained. At a time when vaccine therapy appears to be so promising in dealing with many localised infective conditions the prompt isolation of the causal micro-organism becomes a point of paramount importance. When the affected organ is the lung the particular investigation here referred to may be the sole means of obtaining the necessary culture from which to prepare the vaccine.

Harley-street, W.

THE DYSPEPSIA OF OLD AGE.

BY W. SOLTAU FENWICK, M.D. LOND., SENIOR PHYSICIAN, THE LONDON TEMPERANCE HOSPITAL.

AFTER 65 years of age functional disorders of digestion become extremely common, and even when no abnormal symptoms exist old people usually suffer from an enfeebled or capricious appetite and find that they can only avoid indigestion by the observance of a limited dietary. As the result of a laborious statistical inquiry into the relative frequency of various forms of dyspepsia at different periods of life, Samuel Fenwick found that 21 per cent. of all persons over 65 years of age suffered more or less from chronic indigestion. My own investigations, while generally confirming this estimate, have been more directly concerned with the causation of the digestive complaints met with in advanced life, and seem to indicate that out of every 100 cases of chronic dyspepsia in persons over 65 years of age 66 are secondary to organic disease of some important organ of the body, while the remaining 34 owe their symptoms to a progressive degeneration of the secretory structures of the stomach and intestines. In the former class the disorder of digestion usually takes the form of a chronic gastritis due to disease of the kidneys, prostate gland, heart, lungs, liver, pancreas, chronic gout, or inefficient mastication, while in about 7 of the 66 cases, or in 10 6 per cent. of the entire number, longcontinued hypersecretion due to chronic ulcer in the vicinity of the pylorus, gall-stones, or diseased appendix is the cause of the constant indigestion. The true dyspepsia of old age, which depends upon a series of retrograde changes in the alimentary tract, has hitherto received little or no attention, and I am consequently obliged to rely upon my own observations for the following notes upon the subject.

Pathology.

Some years ago, while pursuing with von Recklinghausen a histological investigation of stomachs taken from persons who had died from different complaints, I was much struck by certain morbid appearances presented by the organ in the case of old persons who had died either from an accident or some acute disease and in whom the other viscera of the body were quite healthy. Further investigations have fully confirmed these earlier impressions, and it is now quite certain that with advancing age a progressive degeneration affects the secretory structures of the entire digestive canal. Although after the age of 50 these changes are fairly constant, careful examination will often detect their existence at a much earlier period, and in one instance

¹ This case was fully reported by Mr. Newbolt in the Liverpool Medico-Chirurgical Journal for January, 1907.

[Nov. 6, 1909. 1347

they were extremely well marked in a man in his forty-first year. To the naked eye the pyloric third of the stomach presents an attenuated appearance, the rugæ being practically absent and the mucous membrane abnormally smooth, pigmented in patches, and firmly adherent to the subjacent muscular coat. The pyloric orifice is also less patent than usual and readily tears when stretched. In more advanced cases glistening lines or streaks may be observed running parallel to the lesser curvature, or irregular patches of thin, scar-like tissue are scattered over the mucous membrane near the pylorus. In such it is usual to find that the walls of the stomach are so thin and white as to resemble tissue paper, while from the size of the organ it is obvious that a considerable degree of gastrectasis must have existed during life. Post-mortem digestion is rarely encountered. rule, the small intestines exhibit the same pallid, thin, and inelastic appearance, while the colon is distended with gas and unusually translucent. Extensive atheroma of the abdominal aorta, coronary and mesenteric arteries may usually be

On microscopical examination of the pyloric region the first sign of disease is found to consist of an overgrowth of the connective tissue that surrounds and supports the tubular glands, with the result that the latter appear attenuated and unduly separated from one another. Even at an early stage of the disease the columnar epithelium which covers the surface of the mucosa and lines the mouths of the ducts has disappeared and the cells of the glands have lost their individual outlines and present a granular appearance. As the disease progresses the ever-increasing interstitial tissue twists, distorts, and finally compresses the glandular structures until their extreme fundi are merely represented by a series of minute cysts lined by a cubical endothelium. Finally these disappear and the mucous membrane is converted into a thin layer of fibrous tissue. Coincidently with these changes in the mucosa the submucous coat suffers from a similar but less intense form of cirrhosis, accompanied by an obliterative arteritis of its nutrient vessels, with the result that the intervening muscularis mucosæ becomes more or less destroyed by compression. At first the muscular tunic shows signs of hypertrophy, but sooner or later it also becomes involved by an interstitial fibrosis and its contractile fibres either atrophy or are affected by a fatty degeneration. Unlike the similar condition which results from ordinary interstitial gastritis, indications of hyperæmia are absent and the peritoneal coat is never thickened. The cirrhotic changes rarely extend beyond the central zone of the stomach; indeed, the connective tissue of the fundus is usually very thin and fragile in appearance, while the glands are either dilated and devoid of cells or are incompletely filled by globules of fat. In the small intestine the villi are markedly shrunken and distorted, and the follicles of Lieberkühn are filled with masses of degenerated cells, while in advanced cases the mucous membrane is more or less completely destroyed by an interstitial fibrosis. Changes of a similar character are almost always present in the colon, and the head of the pancreas is usually atrophied or fatty.

If one may argue from the somewhat similar changes which affect the gastro-intestinal tract in cases of chronic interstitial nephritis, pernicious anemia, and diabetes, it would seem probable that the atrophy of the alimentary organs which occurs in old age is the expression of a mild but chronic toxemia, the poisons of which produce irritation during their elimination by the glands of the gastric and intestinal mucous membranes, and are themselves possibly produced by some abnormal chemical changes in the contents of the large bowel.

With regard to the chemistry of digestion in this condition, I have usually found that the total acidity of the gastric contents after a test breakfast is less than normal, and varies between 30 and 45. Free hydrochloric acid is never met with and the proteid acid is also diminished in amount. Lactic acid is never present. At an advanced stage of the disease the motility of the stomach becomes much impaired, but undigested food is never found in the viscus in the early morning.

Symptoms.

The dyspepsia of old age is common to all classes of the community, but is rather more frequent in women than in men. It usually develops between 60 and 70 years of age and gradually increases in severity with advancing formed in an efficient manner, and new teeth should be

years. As a rule the symptoms commence in an insidious manner, but occasionally their onset is somewhat abrupt and dates from an accident or an acute illness. Flatulence invariably constitutes the most prominent symptom of the complaint. On rising from bed in the morning a sense of fulness, weight, or distension is usually experienced in the upper part of the abdomen, accompanied, perhaps, by nausea, giddiness, or palpitation, and not infrequently followed by an attack of retching which serves to expel a quantity of odourless gas from the stomach. As time goes on it is noticed that the appetite for breakfast steadily diminishes and articles of food which were previously enjoyed are renounced one after another until a piece of toast or a few thin slices of bread and butter constitute the entire meal. At midday the desire for food is more pronounced and a fairly substantial meal may be taken with relish, but during the afternoon epigastric discomfort, eructations of gas, and a marked disinclination to mental work frequently manifest With the progress of time the sense of general discomfort becomes gradually augmented and it is found that abdominal distension and gaseous eructations are almost constantly present, although the individual himself is often oblivious of the constant noisy belchings or borborygmi which annoy his acquaintances and distress his relatives. Occasionally pyrosis, preceded by a cramping pain in the epigastrium, is a troublesome symptom, but regurgitations of an acid fluid into the throat are rarely the subject of complaint. Nausea and retching after food are by no means infrequent, but vomiting is seldom observed. Palpitation of the heart, flushing of the face, tightness of the chest, and a difficulty of inspiration are common in stout persons and greatly add to the general distress. The flatulence is often particularly severe at night and for some hours the patient may be obliged to sit up in bed and to make frequent and varied efforts to expel the gas from his stomach. These nocturnal attacks are particularly common in persons who partake of a light meal of liquid or semi-solid material before going to bed. The bowels are always sluggish in their action and the stools are hard, deficient in colour, and evacuated with difficulty. Anal prolapse develops in many instances, but piles are rarely met

These symptoms may exist in varying degrees of severity for many years, during which the individual maintains his physical strength in a surprising manner and suffers but slight loss of weight. He usually finds, however, that breathlessness ensues upon exertion and that mental worry or anxiety or physical fatigue will at once induce a severe attack of flatulence even in the absence of food. gradually the indications of intestinal disturbance manifest themselves, and when these become established the failure of nutrition at once attracts attention. Week by week the body diminishes in weight, the lips and conjunctive become pallid, the skin loses its elasticity, and presents a dry, scurfy appearance, and there is a rapid deterioration of both the physical and mental powers. The patient now constantly wakes about 5 o'clock in the morning with colicky pains in the left side of the abdomen, and a call to stool results in the expulsion of much flatus and perhaps a little opalescent fluid. In some cases, and more especially in men, the pressure of the distended intestines upon the bladder induces a frequent desire to micturate, while the passage of flatus is often attended by dribbling of urine. The constipation which had previously been a marked feature of the case is interrupted by attacks of diarrhoa, which although not severe are productive of great debility and are followed by further impairment of the appetite and persistent dryness of the tongue. These symptoms, while they continue to exhibit a progressive character, are relieved to some extent by a residence in a bracing locality, careful dieting, and cheerful companionship, but are exaggerated by a damp atmosphere and by indulgence in liquid food. In some instances cardiac failure or an attack of diarrhoea brings life to a sudden termination, but as a rule death ensues from general exhaustion after a period of unconsciousness.

Treatment.

The treatment of senile dyspepsia is essentially the same as that adopted in the allied conditions of achylia gastrica and atrophy of the stomach. Mastication must be perinserted when necessary. The state of the mouth requires careful attention, and a wash composed of Condy's fluid, boric acid, or other antiseptic should be employed after each meal. Special precautions must be taken to protect the patient from exposure to cold, and it is advisable that a woollen or flannel belt be worn next to the skin of the abdomen both summer and winter. Fluids always increase the tendency to flatulence, and consequently beef-tea, broths. and soups should be avoided, and only a small quantity of hot water be allowed at the end of the principal meal. Tea always disagrees, and the various sweet preparations of cocoa are apt to excite gastric fermentation; but a palatable beverage may be prepared from the cocoa nibs or husks. Some individuals are able to take coffee without discomfort. The addition of a tablespoonful of brandy or whisky to the hot water taken after meals is often of value in allaying the epigastric distension, but wines, malt liquors, and effervescent drinks must be avoided. Raw milk should be prescribed with caution, and in most cases it requires to be diluted with limewater, mixed with citrate of sodium or peptonised, before the patient can digest it. The fact that subacidity always exists renders it necessary to restrict the diet to finely minced white fish, chicken, game, brains, tripe, sweetbreads, calves' feet, eggs, and scraped or pounded raw meat. Green vegetables and raw fruits always increase the indigestion, but cauliflower, seakale, stewed celery, and asparagus may be given in moderation, or a baked apple may be taken with the midday meal. Toast is preferable to bread, while buns, cake, and pastry must be prohibited. Fats may be allowed in mild cases and cod-liver oil is often of much benefit, but in advanced cases fatty substances are apt to produce nausea and diarrhea. The various digested and semi-digested cereal foods, maltine, and sanatogen help to vary the diet, but barley, oatmeal, and rice must be given with caution.

The main indications for medicinal treatment are to correct the subacidity and to relieve the flatulence and constipation. For deficient digestive power of the stomach it is customary to prescribe dilute hydrochloric acid after meals in combination with pepsin, papain, or other artificial digestives, but when given in the ordinary way the mineral acid seldom produces any good effect, while pepsin and its allies are useless. A better plan is to administer 6 onnces or more of a 0.05 per cent. solution of hydrochloric acid, combined with one and a half drachms of glycerine twice a day after the principal meals. As a rule, the best aid to gastric digestion is to be found in the administration of lactic acid bacilli in the form of Metchnikoff's sour milk. If this is properly prepared and a tumblerful be taken with the meals each day many of the dyspeptic phenomena vanish after about a fortnight and the flatulence is greatly relieved. According to my experience the various tablets composed of lactic acid bacilli at present on the market are of very little value. Maltine and takadiastase are chiefly of use when intestinal dyspepsia exists and should be given with the meals. Tonics always increase the flatulence and even the various bitters prescribed with the view of stimulating the appetite usually disagree after a few days. In order to relieve an attack of flatulence a draught containing ammonia, ether, and spirit of cajuput is usually employed, but a far better remedy is to be found in the alcoholic essence of peppermint introduced by Ricqlès and now obtainable at most of the large chemists in London. One teaspoonful or less in a sherry-glassful of water seldom fails to relieve the feeling of distension or an attack of wind colic. For the constipation salines and mineral waters should be avoided, and recourse be had to a mixture of cascara and maltine, a confection of sulphur and guaiacum, the infusion of senna pods, or to an occasional dose of grey powder.

Harley-street, W.

SUSSEX COUNTY HOSPITAL, BRIGHTON.—The elective committee of the Sussex County Hospital on Oct. 27th received with the greatest regret the resignation of Mr. T. Jenner Verrall, senior honorary surgeon, after 24½ years' service in connexion with the institution. The committee recognised the great value that his services have been to the hospital, and the unvarying care and attention that he always paid to the patients under his charge. Mr. Verrall was appointed an honorary consulting surgeon, and Mr. A. H. Buck, senior assistant surgeon, was appointed surgeon. Mr. H. N. Fletcher was appointed assistant surgeon.

SINUSITIS OCCURRING AS A CON-COMITANT COMPLICATION OF INFLUENZA.¹

BY R. M. MANWARING-WHITE, M.D. EDIN., HONORARY SURGEON TO THE VICTORIA INFIRMARY, NORTHWICH.

In previous epidemics I had noticed the complication of a catarrhal condition of the accessory sinuses of the nose, and so I made a careful study of it during the recent epidemic of influenza which we had in this district. The efficient treatment of this simple complication gives such relief to the patient and engenders such thanks that I thought it suitable for a short paper.

Influenza, to our knowledge, has visited this country in epidemics for very many years. In text-books published previous to 1908 no mention is made of sinusitis; are we then dealing with a new complication, or did it occur and was unrecognised? On looking through the literature I think we have distinct evidence of its presence in former epidemics, but still it cannot have been common until the last few years. During last winter the greater number of those suffering from influenza had also sinusitis, but in many instances treatment for the complication was unnecessary. It first came under my notice in 1906-07, and attracted attention by the extraordinary daily attack of acute pain occurring at the same hour. In my experience it is more common in men than in women, and does not occur in children, due to the fact that the sinuses do not develop until puberty.

Etiology. -Sinusitis is not necessarily influenzal in origin. but might be due to any severe acute catarrh. The micrococcus catarrhalis is the organism now usually present in cases of clinical influenza. I examined the nasal discharge of a number of cases during the last epidemic and usually found the micrococcus catarrhalis, but not in a single instance could I demonstrate the Pfeiffer bacillus. The nasal mucous membrane is very liable to catarrh, and its continuity with the accessory cavities renders the latter prone to the same conditions by simple extension of the catarrhal process, then organismal infection readily occurs. The method of infection I believe to be by inhalation rather than from the blood stream. Air inhaled for the greater part passes into the nostrils vertically, and the largest stream passes along the middle meatus, in which we have the opening of the frontal sinus. Another and smaller stream passes up to the superior meatus and enters the sphenoidal sinus. This latter stream is very much slower than the former. Thus it is that the frontal sinus is more liable to infection than the other accessory cavities. We must not, however, lose sight of the fact that it appears to be almost impossible in many cases of apparent frontal sinusitis to state that the anterior ethmoidal cells are free from disease. Waggett says that in all cases of frontal sinusitis we may conclude that the anterior ethmoidal cells are also affected. Similarly, in infection of the sphenoidal sinus there is also infection of the posterior

ethmoidal cells.

Symptoms. - The symptoms of an inflammatory condition of the accessory sinuses of the nose are considerably modified according as the ostium of the cavity remains patent or becomes at times closed from swelling of its mucous membrane. In the former case a spontaneous cure results, while in the latter there is retention and consequent aggravation of the symptoms. In considering the frontal sinus we must remember that we are also probably dealing with the anterior ethmoidal cells. The attack of influenza is ushered in with the usual aching of the limbs, back, and head, and the other cardinal symptoms. On the next day the headache appears to be concentrated in the frontal region, and we get a watery discharge from the nose, sometimes almost entirely unilateral. On the third day the headache increases in severity and is described as neuralgia in the course of the supraorbital nerve with often deep-seated pain around and in the orbit. Whereas during the preceding days it was continuous, the pain now comes on at practically the same hour each day and passes off again in three or four hours; during the rest of the day the patient is more or less free from

¹ A paper read before the Lancashire and Cheshire Branch (Altrincham Division) of the British Medical Association.

trouble, but on the following day the pain returns at the same hour and lasts about the same time. Occasionally the attacks occur two or three times during the day but more usually there is only one attack, which in the large majority of cases commences about 10 A.M. and lasts until about 1 P.M.

These pains are peculiarly aggravated by straining, coughing, and blowing the nose or by sneezing, unless by so doing there is a copious discharge, which of course affords relief. The cessation of pain frequently occurs pari passu with the discharge from the nose. The discharge, which was at first watery, is now thick and purulent and contains yellow particles in it, like the sulphur-yellow granules of actinomycotic pus. At other times the discharge is homogeneous in consistence and of a canary-yellow colour; frequently also we find streaks of blood present, due possibly to the violent attempts made to blow the nose. Percussion over the affected sinus is extremely painful, and the difference on the two sides is most marked. In a few cases I have been able to demonstrate on percussion a distinct dull note on the affected side, as compared with the marked resonance of the bone on the healthy side. In very aggravated cases I have seen a slight cedema and redness of the skin over the affected side, also of the eyelid and conjunctiva. Pressure on the supraorbital foramen, and rarely also on the infraorbital foramen, excites the most acute pain.

The symptoms continue for some days, in a few cases disappearing about the end of the first week, but more usually persisting for from 10 to 14 days. After that time they usually gradually subside, the yellow discolouration disappearing from the discharge, which also becomes more watery. In some cases the yellow purulent material and a watery discharge seem to alternate. In one case when the trouble disappeared from one side it commenced in the other. In two cases extension occurred to the ear-I presume along the Eustachian tube possibly due to violent attempts to blow the nose; in the one case followed by an otorrhea and in the other only by deafness, tinnitus, and otalgia, with injection of the tympanum, which disappeared in a few days, and the hearing gradually returned. StClair Thomson records a case of tense ædema without redness of the right eyelid, and tenderness of the upper and inner angle of the right orbit. No pus could ever be discovered in the nose, yet on incising the swelling there was an escape of free fluid pus welling out from the frontal sinus and containing the micrococcus catarrhalis in pure culture. The pain may not disappear entirely with the cessation of the discharge, but may continue for two or three months; this, however, is quite unusual.

Sphenoidal sinusitis.—This probably never occurs without infection also of the posterior ethmoidal cells. Suppuration in these sinuses is not nearly so common as in the frontal, and I have only met with two cases and one of these was doubtful The pain, as in frontal infection, is periodic, but is situated mostly in the occipital region; it may be present on the vertex and at the back of the eyes, and described by one patient like a hundred needles pricking the back of the eye. The discharge passes into the superior meatus and from there into the pharynx, and the patient is continually expectorating: it is very similar in consistence and colour to that observed in frontal sinusitis. Through irritation of the pharynx there is produced a most hacking and persistent cough. At times during the acute pain there may be marked somnolence, the patient being in a dazed condition. When we realise how near to important structures at the base of the brain the sphenoidal sinus is situated, it seems easy to imagine most untoward symptoms. There are usually conjunctivitis and cedema of the eyelid, and vision may be affected. It has been reported that optic neuritis and total blindness may occur, due to the pressure on the optic nerve as it passes through the wall of the sphenoidal sinus. The condition of one of the patients I saw appeared to be so serious that the relatives thought he had had a stroke, and for some weeks I did not recognise the true nature of the condition.

Maxillary sinusitis occurring during an attack of influenza is rare compared to frontal infection. I have only met with two cases which I could definitely say were influenzal in origin, and this I consider rather tends to prove that the vast majority of cases of antral disease with which we meet are dental in origin. The usual symptoms of antral suppuration are present, including swelling and cedema of the

cheek, but the pain differs from that which occurs in frontal sinusitis by not being so markedly periodic, although it also has that tendency. The character of the discharge is similar to that which occurs from the frontal sinus under the same conditions.

Diagnosis. - Given a case of influenza, if there is unilateral nasal discharge with periodic headache coming on at the same hour each day, we may safely conclude that we have to deal with suppuration in one of the accessory sinuses of the nose. To differentiate the sinus involved the locality of the pain is of great importance in giving us a clue to the seat of infection and usually definitely settles the question. If there is any doubt the best method is afforded by anterior rhinoscopy; if after thoroughly cleansing the nose we find pus oozing into the middle meatus, then it is either coming from the antrum or from the frontal and anterior ethmoidal cells, whereas pus in the superior meatus must necessarily come from the sphenoidal sinus and the posterior ethmoidal Transillumination will readily distinguish frontal from antral disease, in a healthy antrum the bright light under the orbit and the red glare of the pupil being particularly noted. Other methods, such as puncture of the antrum with introduction of a cannula, and X ray photographs are quite unnecessary.

Prognosis.—I have only seen one case of sinusitis occurring as a complication of influenza which became chronic, and that did not seem severe enough to suggest operative treatment. The majority appear to be quite cured in a week to ten days, a few cases persist for two or three weeks, and I know of one which has persisted for about three months. Many patients recover without any treatment at all, and few would pass into the chronic stage if efficient local treatment was adopted during the early stages of the attack. The least favourable cases are those where free drainage from the sinus is hindered by some form of nasal obstruction.

Treatment. - Unlike a large number of diseases with which we have to deal, very great benefit is derived from treatment. The one case which I have mentioned as becoming chronic I saw more than two years ago, before I realised the rationale of the treatment. At first I tried tobacco snuff, from which some of the patients derived considerable benefit, also in addition an atomiser used frequently with a chloretone and menthol mixture was useful, but I rather believe the case of otalgia, to which I have referred, was caused by too violent use of this instrument. I have in consequence now quite discarded it. Last year I had one case which received no benefit from this treatment, and he consulted a surgeon who wrote to me confirming my diagnosis, and suggested the passage of a probe daily into the frontal sinus, The passage of a and if this failed operative treatment. cannula into the frontal sinus is an extremely difficult procedure, which Tilley says can only be acquired by considerable practice coupled with an intimate knowledge of the nasal fossæ and their accessory sinuses. The patient mentioned, I may add, recovered without the passage of a cannula or operative interference.

The treatment which I now always adopt is as follows, and luckily it appears to suit all the accessory sinuses equally well. Hot fomentations are applied over the affected side, and a teaspoonful of the following mixture is put in a jug of boiling water, and the vapour is inhaled every three hours, a towel being placed over the head to concentrate the vapour as much as possible: 5 minims of oil of eucalyptus, ½ drachm of menthol, ounce of rectified spirit, and methylated spirit to make up 14 ounces. This treatment relieves the pain and usually stimulates a free discharge from the nose, and the patients say "it clears the head." If unsuccessful, but I have never found it fail, I should pack the neighbourhood of the middle meatus with cocaine and adrenalin. In antral suppuration I should also recommend that the head be kept low as much as possible and on the opposite side so as to secure more efficient drainage. Sandeman has invented a modified Politzer bag which is first emptied of air, the nostrils closed tightly, and the bag allowed to expand suddenly as the patient svallows, but it is difficult to understand how the method can be of practical value when used in a congested nasal cavity. Some relief of pain may be procured by the internal administration of such drugs as aspirin. phenacetin, &c. When the soft tissues over the sinus become red, swollen, ædematous, and very painful on pressure it may be assumed, in the case of the

frontal sinus, that the fronto-nasal duct is obstructed and that pus is making its way through the walls of the sinus, and if the treatment above mentioned fails it then becomes the duty of the surgeon to open the sinus from the outside. Both Tilley and StClair Thomson record cases in which operative interference has been necessary, but so far I have not met one.

Northwich.

A CASE OF TERTIARY SYPHILIS TER-MINATING IN SUDDEN DEATH FROM ABDUCTOR PARALYSIS OF THE VOCAL CORDS.

BY ROBLEY H. J. BROWNE, L.R.C.P. LOND., M.R.C.S. ENG., FLEET SURGEON, ROYAL NAVY.

An able seaman, aged 30 years, was placed on the sick list on Sept. 9th with partial aphonia; there was also some dyspnœa, which was said to have been noticed for "about a month." The patient had in addition well-marked ozena; the bridge of the nose was sunken. There was a history of complete syphilis dating back to 1902; the man had been several times under treatment, both on board ship and in hospital. On examination of the chest the entry of air was fair on both sides, but less satisfactory on the left side than on the right. The heart sounds were not quite normal, the second sound being unduly accentuated; this suggested the possibility of aneurysmal mischief. The aphonia passed off in two or three days, and a cough cleared up almost entirely. Treatment included inhalations of steam with entirely. Treatment included inhalations of steam with tinctura benzoini and the internal administration of a mixture containing 1-16th of a grain of perchloride of mercury and 10 grains of potassium iodide. On Sept. 15th he expressed himself as fit for duty and was allowed to try.

On the 18th the man came again, having woke up in the middle of the night "feeling ill." There were considerable dyspnæa and a rise of temperature (100 8° F.). He was put in bed (on milk diet) and the mistura biniodidi was repeated every 4 hours, the inhaler being again used. Whilst doing duty he had been taking a draught every morning containing 15 grains of potassium iodide and 3 minims of liquor iodi in 4 ounces of water, as originally recommended (I believe) by Larrieu. On the afternoon of the 18th there was some alarming dyspnœa, and the temperature rose to 103°. By the following morning the dyspnœa had passed off almost entirely and the temperature was normal; the patient got rid of some thick purulent sputum with much relief. The general condition rapidly improved; the temperature kept normal, the pulse averaged 80, and the respirations 20; there were no developments in the chest symptoms The voice was still rather weak, but was much stronger than when he was first seen. There was some paroxysmal dyspnœa which disappeared after he had, with difficulty, expectorated the tenacious pus referred to above; this took place two or three times a day. The man was, in my opinion, a most undesirable person to retain under the my opinion, a most undesirable person to retain under the conditions of life on board ship, and I was arranging to send him to hospital in a ship which was to leave Cromarty (where we were at the time) on the 25th. With that object in view he was allowed to get up for half a day on the 23rd, and for the greater part of the 24th. He took food well, and expressed times! (on the carning of the 24th). himself (on the evening of the 24th) as quite fit for the journey on the following day. Shortly after midnight (24th-25th) he apparently woke up, got out of bed, and (pointing to his throat) shook a patient in the next bed who called a sick-berth steward sleeping close by. The patient had by this time returned to a chair alongside his bed, where he immediately collapsed. I was at once summoned, and arriving at the sick bay very shortly after the seizure found the man dead. The face was congested but not cyanosed, the heart had stopped, and further measures (artificial respiration and injection of strychnine) were futile. The congestion of the face passed off very quickly and air was twice heard to escape from the larynx with a sibilant noise.

Necropsy. - A post-mortem examination was made on the following day by Surgeon L. C. Hunt and myself, when the

following lesions were found. On examining the larynx the cords were seen to be in the "cadaveric position"; they were thickened, and there was some scarring in the neighbourhood, the result of old ulceration; this extended up towards the base of the epiglottis. The trachea was extensively scarred and ulcerated, with cicatricial tissue in several places; there was gradual narrowing of the lumen, and 3 inches below the larynx there was a tight annular stricture, which would just admit a No. 7 bougie. Below this stricture the ulceration and contraction extended down the trachea into both bronchi; a succession of pus-bathed ulcers were found in this position, the left side being more affected than the right. The lung tissue was normal. The right side of the heart was full of blood, suggesting the prior cessation of respiration. There was some thickening of the mitral valve, and a few patches of commencing atheroma of the aorta were seen. Several glands in the neck were enlarged, and one or two near the bifurcation of the trachea were breaking down (gummatous).

Taking into consideration the clinical symptoms and the post-mortem appearances, I am of opinion that the immediate cause of death was abductor paralysis of the vocal cords. In a recent clinical lecture by Dr. Herbert French 1 the following passage occurs: "Paralysis of vocal cords may be a cause of sudden death. In syphilitic subjects particularly, special portions of the brain may suffer from nerve-cell degeneration. If the centre controlling the movements of the vocal cords is attacked, it is a most unfortunate fact that it is always the abductor muscles of the larynx which get paralysed first, so that before the adductors become paralysed there may be a sudden bringing together of the cords by adductor spasm, and unless tracheotomy is performed instantly the patient cannot breathe, and death occurs as certainly as if he were killed by strangulation." In this case of course it is more probable that the recurrent laryngeal may have been directly involved in some of the diseased structures, but this was not actually demonstrated at the post-mortem examination. When first called to the man I thought it most probable that an undetected aneurysm had burst, and I must admit that (in the absence of cyanosis or other evidence of respiratory obstruction) I did not consider the question of tracheotomy. However, I have not the slightest doubt that the patient was dead beyond recall when I reached him, and in any case the presence of a tight tracheal stricture so low down would have rendered the operation futile. The severe lesions discovered post mortem were quite out of proportion to the clinical symptoms and physical signs. Syphilitic disease of this type is fortunately very rare, and I consider the case sufficiently interesting to bring forward.

H.M.S. Temeraire.

RAPID RECOVERY IN A CASE OF TROPH-NEUROTIC ANÆMIA BY INTRA-MUSCULAR INJECTIONS OF SODIUM PARA-AMINO-PHENYLARSONATE.

BY T. WILSON PARRY, M.A., M.D. CANTAB.

I WAS urgently sent for, in the late evening of June 26th. 1909, to attend a lady in a dead faint. The history I elicited was the following. She had had a nervous shock in March, 1908, from which she had never properly recovered. Since then she had been going steadily, but surely, down hill. She was 54 years of age, and the mother of 12 children, the youngest living being 20. Having had pains about her body, which she attributed to rheumatism, she went on her own account to Harrogate early in June. She tried drinking some of the sulphur-water and taking one or two baths, but felt so ill afterwards that she abandoned the idea, and a medical man whom she consulted advised her to return home at once, as she was quite unfit to follow any form of hydropathic treatment. It was on her immediate return from Harrogate that I was called in to see her. She had been violently sick, and was only slightly conscious. Her pulse was very small, rapid, and could be obliterated by the most delicate pressure. Her heart sounds were very indistinctly heard, being very

¹ Guy's Hospital Gazette, August 7th.

small and distant, but no murmur could be detected. Her skin was deathly pale with a slight tinge of yellowness, and was markedly dry. The conjunctive were colourless. There was no nystagmus. Her tongue was clean, but sore, and her temperature was 103° F. I could find no organic lesion; nor did I find in the urine any trace of sugar, albumin, or indican.

During the next few days it was my endeavour to stem the sickness of the patient by gastric sedatives, and to bring her stomach into condition for receiving arsenic, as one felt if any drug would do her good it must be this one. On June 29th I attempted arsenic, strychnia, and small doses of iron; and on July 1st she was given calomel (12th grain) three times a day, as an intestinal antiseptic, in case the anæmia was septic in origin. On July 2nd I stopped the mixture I was giving by the mouth, and replaced it by intramuscular injections of sodium para-aminophenylarsonate, an organic salt of arsenic prepared by Messrs. Burroughs, Wellcome, and Co., under the name of "soamin." As it has less than one-fortieth of the toxicity of arsenious acid much larger doses can be given, and results are more quickly obtainable. I injected intramuscularly one grain of this preparation in the morning, and one in the evening of July 2nd. The spot chosen for puncture was a point midway between the anterior superior spine of the ilium and the summit of the intergluteal fold of the buttocks. I injected one side in the morning and the opposite side at night. The injections were only given on alternate days. On July 4th the same two doses were given, and on July 6th two grains were administered in the morning and one at night. The temperature, which had been daily dropping, reached normal on this day and practically continued so for the rest of the time. On July 8th two grains were injected both morning and evening, and these same doses were repeated on July 10th. On July 12th three grains were injected in the morning and two in the evening, and these same doses were repeated on July 14th. On July 16th three grains were given both morning and evening and these doses were continued, on alternate days, till August 9th, when in all 100 grains of the preparation had been injected. During this time the patient was gradually passing from a state of sickness, giddiness, faintness, and amnesia to first toleration of and then satisfaction in taking food. Her vertiginous attacks were at first almost constant, extreme giddiness occurring if she merely turned her head while in the prone position. After a while they occurred only when she sat up, and eventually they disappeared altogether. She told me she could not remember any of the journey from Harrogate home nor any of the events that happened for more than a week after this. After she had been about a fortnight under treatment she was moved from her bed to a couch by an open window and a week later to the garden, where she lay all day in the open air. At the end of a month she could walk a short distance unassisted. On August 19th she went to the seaside, where she continued to improve in a steady and uninterrupted manner.

Dr. Wyatt Wingrave kindly examined the blood for me on June 30th, before the injections of the drug were given, and again on August 9th, after the hundredth grain had been administered. The following are the analyses of the two examinations:—

							Ju	ine 30th.	Au	gust 9th.
Hæmoglo	bin						 65	per cent.	 93	per cent.
Red corpu	iscles						 3	,500,000	 4	,800,000
White	,,							2,800		3,250
Differ	entic	u:								
(a)	Whit	e-								
	Po	lym	orp	hic	cells		 34	per cent.	 55	per cent.
	Mo	onor	nucl	ear	,,		 32	**	 21	,,
	Ly	mp	hocy	ytes			 34	,,	 24	,,
	Eo	sinc	phi	les			 1	,,	 0.5	,,
(b)	Red-	-								
	Po	ikile	ocyt	es				A few.		A few.
	Me	gal	ocyt	es				,,		,,
	Mi	croc	yte	8				,,		,,
	Ch	rom	aph	ile g	gran	ules		,,		,,
	No	rmc	bla	ts				None.		None.
Bacteria								••		,,
Colour inc	lex	•••					 0.9	per cent.	 0.9	per cent.

From the above table several points are clearly demonstrated. As a definite leucopenia was established by the first blood count (only 2800 white cells being found in the cubic millimetre) a diagnosis of both pernicious anæmia and

leucocythæmia could be at once dismissed. The colour-index being slightly below normal was also evidence against the former. As there was a decided diminution in hæmoglobin and also in both red and white corpuscles, the first thing that struck one on looking at the result of the examination was that a severe hæmorrhage had taken place. This, how-ever, was not the case as there had been no bleeding from any part of the body. The next thing noticeable was the large percentage of mononuclear leucocytes which were present in more than double their normal number. No nucleated red cells could be found, but the red corpuscles themselves showed considerable variation in size and shape, megalocytes, microcytes, and polkilocytes all being found. All the evidence, therefore, seemed to suggest a troph-neurotic influence in interfering with the balance and the renewal of the red corpuscles, attributable, no doubt, to the severe mental shock that had been sustained. It has been my lot to have several cases of severe and even fatal anemias, as also cases of diabetes, that have undoubtedly originated in a sudden severe mental shock. When comparing the second column with that of normal blood it will be seen that there is still a slight deficit in hæmoglobin and red cells and also a more noticeable one The polynuclear leucocytes, as also the in white cells. lymphocytes, have regained their normal percentage, but the mononuclear cells are still above their normal. though the state of the blood had not quite regained its healthy normal balance, the case was one that had immensely benefited by the treatment employed; so to the intramuscular injections of this arylarsonate I must perforce attribute the striking clinical and hæmatological changes that had taken place. And all this in so short a period as 39 days.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

MEDICAL SECTION.

Oxaluria.

A MEETING of this section was held on Oct. 26th, Dr.

J. MITCHELL BRUCE being in the chair.

Dr. Robert Maguire read a paper on Oxaluria and the Treatment of Calcium Oxalate Deposit from the Urine, with a Method for the Solution of Calcium Oxalate Calculus whilst in the Urinary Passages, which is printed in this issue of The Lancet (see p. 1333).

Dr. BRUCE said that the paper was a record of very careful work, and the conclusions which Dr. Maguire had felt justified in drawing might be of great clinical importance.

Dr. ROBERT HUTCHISON said that the paper was of great practical interest to physicians. The paper might be divided into two parts, the theoretical and the pathological and practical part. He (Dr. Hutchison) was one of those who were profoundly sceptical of the so-called oxaluria symptom complex. He felt strongly that the creation of this symptom complex was the work of imagination. He pointed out that Dr. Maguire in his paper had not touched on the question of the magnesium salts in the urine, and there were other obscure factors that might come into In regard to the plan followed by Dr. Maguire of giving acid phosphate of soda for some time the result would be to increase the acidity of the urine, but in stone there was a strong tendency for oxalic acid and uric acid to alternate, therefore one would run a risk of throwing down uric acid. So far as he could understand, Dr. Maguire seemed to think that it was possible to clear away the calcium oxalate and then give something to treat the uric acid; but the practical difficulty arose how to know when one layer of the stone had been cleared away so that the next layer was ready for treatment. Concerning the composition of commercial acid phosphate of sodium, he said that at the London Hospital they did not have any great difficulty in procuring commercial preparations that were practically pure.

Dr. H. Beckett-Overy said that persons who appeared perfectly healthy might have a considerable amount of

oxalates in the urine. He described the successful treatment of oxalates by giving the citrates of calcium and soda.

Dr. John Anderson gave details of the case of a young woman who complained of no pain whatever in her left side but did complain of pain in her right side. There were blood discs in the urine and calcium oxalate crystals. By means of X ray photographs 10 irregular shaped calculi were seen in the left kidney and one stone only in the right kidney. These stones were removed at one operation, and the stone in the right kidney that caused the pain was of a flattened discoid form, and the stones in the left kidney that caused no pain were "spiky."

no pain were "spiky."
Dr. NESTOR I. C. TIRARD congratulated Dr. Maguire very warmly on his paper, but wished that the observations therein had been confirmed by further information. It was felt that at present there was some doubt how far the case recorded by Dr. Maguire could be regarded as definitely solving the question of solution of the stone. Dr. Maguire admitted that possibly it was not so much solution as disintegration. With regard to the pharmacology of the subject, they had all been in the habit of using acid phosphate of sodium in treatment in cases of nervous dyspepsia without any definite thought concerning its action as a solvent of oxalic acid. When he (Dr. Tirard) as a solvent of oxalic acid. When he (Dr. Tirard) administered phosphate of sodium it had been usually with some idea of its purgative action or of its action in changing the composition of the urine. If they were to use the drug with some new hope of causing a diminution in the stone in cases of oxalic acid then they would be largely indebted to Dr. Maguire for his observations. But he (Dr. Tirard) would like more cases and more evidence. He admitted, however, that in the one case brought forward by Dr. Maguire the evidence of the pain over the ureter and the history of the hæmaturia appeared almost conclusive. With regard to the purity of commercial acid sodium phosphate the attention of those concerned in the production of the British Pharmacopœia was directed towards the variable amount of the water of crystallisation. He did not think even if there was a variable quantity of water of crystallisation that the chemical action of the compound would thereby be seriously affected.

Dr. MAGUIRE, in reply, observed that in one of the large hospitals at Vienna from 5 to 6 per cent. of the patients were found to have oxalates in the urine. In reference to the impurity of the commercial acid phosphate of sodium he could only say that he had tried the salt from three chemists. There was no doubt that in the acid phosphate of sodium supplied there was more water of crystallisation than it ought to contain.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Presidential Address.—Drug Treatment of Inebriety.— Exhibition of Cases and Specimens.

THE first meeting of the session of this society was held on Oct. 22nd, Dr. J. B. HELLIER, the President, being in the chair.

The PRESIDENT delivered an address on the Medical Student and his Curriculum from a Teacher's Point of View. Mr. W. ASTEN read some notes on the Drug Treatment of Inebriety. The treatment was essentially that first proposed by Dr. McBride, and consisted in the hypodermic injection of atropine and strychnine twice or thrice daily for a month or six weeks, with attention to general hygienic conditions, and tonics by the mouth. At the commencement of the treatment patients were told that its success depended on their regular attendance at the surgery for injections. He described 7 cases, all of them presenting marked degrees of alcoholism, which had been treated in this way. In 5 treatment was commenced in September, 1905, July, 1907, March, 1908 (2 cases), and July, 1909, respectively. These cases had remained cured up to date. In the two other cases relapses had occurred after two months and four years respectively. Mr. Asten strongly urged the desirability of carrying out this treatment wherever practicable, in view of its simplicity, economy, and the favourable results obtained. Several members quoted cases that had been successfully treated by this method.

Mr. H. LITTLEWOOD showed: 1. Six Inches of Sigmoid Flexure thickened from Chronic Diverticulitis, which had led to fistulous openings between the colon, bladder, and the abdominal wall. The patient, a woman, aged 65 years, had

for 20 years passed fæces and flatus per urethram, and fæces and urine through the abdominal wound. At the operation chronic thickening of the sigmoid was found and a funnel-shaped diverticulum opening into the bladder and on to the surface of the body in the left hypogastric region. This was removed and the fistulous openings closed. Some weeks later fæcal material escaped through the abdominal wound and 6 inches of the bowel were then resected and united end to end. The fistulæ remained completely closed. 2. Gall-stones in the Appendix and in an Appendical Abscess. The patient, a man, aged 52 years, had several attacks of gall-stones and some attacks of appendicitis. At the operation an abscess was found containing three gall-stones; a gall-stone was also found in the appendix. There was a softened patch in the appendix wall, but no opening could be found; probably the gall-stones in the abscess were the result of previous attacks, the opening in the appendix having healed. He has made a good recovery.

Mr. G. Constable Hayes showed two cases of Primary Carcinoma of the Middle Ear. 1. A man, aged 47 years, with suppurating discharge from his right ear for eight months. Squamous-celled carcinoma had filled the whole middle ear and mastoid, destroying the roof and infecting the dura mater. 2. A woman, aged 35 years, with suppurating discharge from the right ear since childhood. She showed facial palsy and a suppurating sinus over the middle of the mastoid. A squamous-celled carcinoma filling the middle ear had destroyed all except the outer wall of the mastoid. The growth extended into the posterior fossa.

Dr. T. Wardrop Griffith showed: 1. A case of Amyotrophic Lateral Sclerosis. There was a slight degree of spastic paraplegia with evidence of nuclear disease in the spinal centres of the upper limbs, profound wasting of both sternomastoids, and some weakness of the voice without much alteration in its quality. The left vocal cord was immobile and in the cadaveric position; the abductors of the right cord were paralysed and the adductors weakened. 2. Two cases of Disseminated Sclerosis in young women. In one case when the patient was seen two years previously she could not walk without assistance. In 12 months she improved so much that she was able to play hockey and was regarded by her friends as cured. The symptoms, however, gradually returned, confirming the original diagnosis.

Dr. R. A. VEDALE exhibited a specimen showing numerous diverticula of the sigmoid flexure, with resulting diverticulitis and local peritonitis. Several coils of the small intestine were firmly united to the sigmoid by long-standing adhesions.

Dr. C. OLDFIELD showed two Suppurating Ovarian Cysts from patients who had both had acute abdominal symptoms for 3 or 4 weeks; the organism in the one case was the bacillus mesentericus, and in the other streptococcus in pure cultures. Both cases recovered without infection of peritoneum or abdominal wall.

Mr. A. L. WHITEHEAD showed cases of (1) Lymphocythæmia with Multiple Retinal Hæmorrhages; and (2) Traumatic Detachment of the Retina which was treated by Puncture of the Sciencia.

Mr. MICHAEL A. TEALE and Dr. E. F. TREVELYAN showed a case of an unusual form of Keratitis in a child which had produced extreme photophobia for several years. It was finally treated by tuberculin.

Dr. W. H. MAXWELL TELLING showed a case of Hypertrophic Cirrhosis of the Liver in a child. There was marked clubbing of the fingers and toes.

Mr. J. F. DOBSON showed a specimen of a Cancerous Stricture of the Sigmoid Flexure from a case in which acute obstruction was caused by the impaction of a foreign body.

Cases and specimens were also shown by Mr. H. Collinson, Dr. O. C. Gruner, and Mr. W. Thompson.

MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.

Paroxysmal Tachycardia.—Congenital Patency of Interventrioular Septum.—Optic Neuritis in Middle-Ear Disease.—A Subcutaneous Operation for Hernia.

A MEETING of this society was held on Oct. 22nd, Professor ROBERT MUIR being in the chair.

Dr. J. S. McKendrick read a short paper on Reflexes in Cardiac Disease, with notes of a case of Paroxysmal Tachycardia. At the outset of his paper Dr. McKendrick referred

to the work of Mackenzie on visceral reflexes, and especially drew attention to the reflexes in cardiac disease. Of these the viscero-sensory and viscero-motor reflexes occurring in angina pectoris were discussed, and reference was made to Lee's reflex, the secretory reflexes, and the pilomotor, autonomic, and pupillary reflexes. The case was that of a man, aged 83 years, who for fully a year before his death had attacks of tachycardia and paroxysmal dyspncea, associated with profuse salivation. His lungs and abdominal organs were sound, the urine contained no albumin, and there was no nervous element in the case. The heart, as a rule, was normal in size and there was no valvular disease; but during the periods of paroxysmal tachycardia it became perceptibly enlarged to the left and a systolic mitral murmur could be heard. By the next day the heart had returned to its normal size and all trace of the murmur had gone. The sphygmogram during the quiescent period showed ordinary cardiac arrhythmia with frequent extra systole of the ventricle, and the rate varied from 65 to 75 beats in the minute. During the tachycardial state the pulse was regular, of low tension, and showed well-marked pulsus alternans, the rate being often 150 beats per minute. During each of these seizures, which lasted from ten minutes to several hours, there was a profuse salivary discharge. On analysis this secretion proved to be almost pure saliva, with no gastric elements. It varied in amount from 10 to 25 cubic centimetres in each The blood pressure was never high, averaging from 125 to 135 mm. Hg, and it did not materially vary either during or after the tachycardial seizure. The tendency to low blood pressure, the dilatation of the heart during the attack, and the pulsus alternans all went to prove that the causation of the attack was probably myocardial and due to disturbed contractility. There was no anginoid pain or hyperalgesia of skin or muscle. The salivary flow was believed to be due to a cardiac reflex through the vagus to the nucleus of the fifth nerve, thereby stimulating its lingual branch. Such cases had occasionally been seen by Mackenzie in true angina pectoris, but no case had been found by Dr. McKendrick in medical literature where the salivary flow was an accompaniment of paroxysmal tachycardia. Polygraphic tracings were difficult to obtain owing to the dyspnæa. The patient died suddenly, probably from vagus inhibition. No post-mortem examination was made.

Dr. J. M. COWAN, in reporting a case in which the bruit de Roger was present, pointed out that in the majority of cases of congenital heart disease the lesions are so extensive that death ensues shortly after birth or in early childhood. During life cyanosis is generally well marked and often The defects are frequently multiple, and an obtrusive. accurate diagnosis is usually possible only on post-mortem examination. Cases, however, occur in which the defect is single, unaccompanied by cyanosis, not incompatible with average health, and associated with distinctive physical signs. Such a defect is the persistence of a communication between the ventricles, a condition described by Henri Roger 30 years ago, and present in the case reported by Dr. Cowan as follows. The patient, an engineman, aged 44 years, was admitted to the Glasgow Royal Infirmary on Dec. 18th, 1908, complaining of swelling of the face of three months', and of the feet of two months', duration. He had never suffered previously from any ill health. On admission he was slightly cedematous and notably anemic. His urine contained albumin and blood in abundance, with hyaline and granular casts.
Under treatment the symptoms rapidly subsided and he was dismissed in fair health on Feb. 21st, 1909. For two or three weeks he remained fairly well, but symptoms recurred and he was readmitted on March 21st with general anasarca and notable dyspnæa. The symptoms gradually progressed, infarct of the lung ensued, and he died on April 1st. The main interest of the case lay in the cardiac lesions. On admission it was noted that the apex impulse was diffuse but not well sustained, and was palpable in the fourth and fifth left interspaces. A long, fairly harsh systolic murmur was audible all over the cardiac area. It was heard best down the left margin and at the foot of the sternum, was fairly well heard at the apex, and was conducted to the axilla and the left scapular angle. It was not conducted into the carotids or towards the left shoulder. The second aortic sound was clear and distinct, but no second sound was heard on auscultation over the ventricles nor at the xiphoid cartilage. The murmur thus closely corresponded to the original description of it by Roger (Académie

de Médecine, 1879) which Dr. Cowan quoted. Its distribution made it certain that the mitral valve was incompetent, and a jugular tracing showed well-marked tricuspid regurgitation, but the maximum intensity of the murmur at the left xiphoid margin and the absence of the second sounds over the ventricles were during life unexplained. Post-mortem examination showed the heart much enlarged, all its cavities dilated, especially the left auricle and ventricle, and the left ventricular wall greatly thickened. The aorta showed some atheromatous patches, and the aortic cusps were a little thickened. At the anterior angle of the membranous septum was a conical aperture about one-eighth of an inch in diameter, surrounded by thickened hard cicatricial tissue surmounted by a few fresh vegetations. The mitral valve was dilated, admitting three fingers. In the anterior cusp was an aperture surrounded on its auricular surface by fresh granulations. Similar granulations occurred on the corresponding surface of the posterior cusp. The foramen ovale was not occluded. The tricuspid valve was dilated, admitting four fingers; its anterior cusp was thickened, shortened, and hardened, and the underlying ventricular wall was thickened and in part covered with fresh granulations. The infundibulum was enlarged and the pulmonary valves were normal. The pericardial sac contained some fluid and a free tag of recent fibrin. There was an infarct of the left lung and a recent pleurisy. The capsules of the kidneys were slightly adherent; there was well-marked parenchymatous nephritis; there were two pelves in the right kidney.

Dr. J. ROWAN and Dr. J. STODDART BARR reported upon a further investigation into the frequency and significance of optic neuritis and other vascular changes in the retine of patients suffering from purulent disease of the middle ear.

Dr. A. G. FAULDS read a short paper upon the Operative Treatment of Hernia in Boys, in which he recommended, as an alternative to the usual open operation for radical cure, the following procedure: (1) reduction of the hernia; (2) insertion of the operator's left forefinger into the canal by invagination of the scrotum; (3) transfixion of both pillars of the ring by one or two ligatures passed subcutaneously; and (4) occlusion of the ring by the drawing tight and tying of these ligatures. Gratifying results were claimed for the operation, which, however, had not proved invariably successful.

Bradford Medico-Chirurgical Society.—The opening meeting of this society was held on Oct. 19th, when Dr. W. Ward-Smith, the President, delivered Some Remarks on the Commoner Deformities of the Lower Extremity due to Rickets, with Especial Regard to their Treatment. After briefly reviewing the general treatment of rickets the President passed on to the consideration of knock-knee, bowlegs, and coxa vara. The treatment of these conditions depended upon (1) the age of the patient; (2) the extent of the deformity; and (3) the circumstances and surroundings. No operative procedure should be adopted until the active general symptoms of rickets had subsided. There was a strong tendency to natural correction. Enormous benefit could be derived from proper local non-operative treatment while the bones were soft. Treatment might be tabulated as follows: (1) rest and recumbency with daily massage and passive movements; (2) rest with fixation of the limb and an apparatus providing pressure; (3) apparatus supporting the limb and permitting application of pressure and yet allowing the patient to walk; and (4) operative. In the youngest children the first method of treatment was usually sufficient. In more advanced cases, in knock-knee, a light wooden external splint should be applied, extending from the upper part of the thigh to 3 inches below the sole of the foot. means of a wide strap the knee was drawn firmly to the splint. This splint could be daily removed for massage and passive movement. In bow-legs the splint was placed on the inner side of the legs. In older children between the ages of 2 and 6 some form of ambulant splint should be used. The best form was an external iron extending from the pelvis to the heel of the boot. A joint at the knee and ankle permitted antero-posterior movements at these points. A broad soft band taking a wide grip of the knee drew it towards the brace. When the patient had passed the age of six years osteotomy was indicated. After describing the various operations of osteotomy and the after-treatment the President then went on to speak of coxa vara. He spoke first of the anatomical condition existing in that deformity. There was a serious limitation of т 3

the movement of abduction of the lower limb, due to (1) the contact of the neck and great trochanter with the margin of the acetabulum; (2) tension on the lower part of the capsule of the joint; and (3) the adaptive contractures of muscles and fascize on the inner side of the thigh. It was more often unilateral than bilateral, and more than 75 per cent. occurred The affected limb appeared to be shorter, and in advanced cases was shorter than the normal side. The great trochanter was higher and more prominent than on the sound side. The diagnosis from morbus corrected on the following points: (1) the gait was usually erect, net with the body bent forwards, as in morbus come; (2) the pain was in the groin, not referred to the thigh or the knee; no "starting pains" (3) there were flexion and external rotation as against adduction and internal rotation in hip disease; and (4) absence of involuntary muscular spasm so frequent in hip disease. The X rays would always clear up a doubtful case. Treatment was at first preventive—general and medicinal treatment of rickets. The local treatment aimed at removing the body weight from the hip: rest with recumbency or an instrument which would conduct the weight of the body through the pelvis. Thomas's knee splint with the bars fixed into a swivel in the heel of the boot, permitting movement of the ankles, was the best instrument. In some cases where the bone was yet soft forcible abduction of the thigh under an anæsthetic might be employed. The limb was then put up in plaster-of-Paris in a position of abduction for some weeks, and for five or six months subsequently treated on a Thomas's knee splint. If these measures failed osteotomy should be employed, usually sub-trochanteric. In conclusion, the President expressed his thanks to Mr. W. H. Thompson and Mr. Norman G. Meade, who had generously permitted him the use of their cases and beds at the Children's Hospital, and to his brother, who, from his association during the last two years with Mr. Robert Jones of Liverpool, had been able to give him considerable help in regard to many points in coxa vara and in the use of Thomas's splints.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on Oct. 29th, Mr. C. Gordon Watson, the President, being in the chair. - Dr. W. Langdon Brown read a paper on Some Intestinal Intoxications and Infections. He said that the infant started with a sterile alimentary canal but speedily acquired bacteria there, chiefly organisms derived from the skin of the nipple. In bottle-fed children there were many more organisms of the bacillus coli class. In children and adolescents there was slight evidence of putrefaction shown by little indican and ethereal sulphates in the urine, while in middle life the putrefactive processes were more abundant. The bowel had three lines of defence: epithelial resistance, bactericidal resistance in blood, and antitoxic resistance in the liver. The great seat of putrefactive change was the large intestine. Proteins putrefy, carbohydrates ferment, and to a certain extent these two processes were antagonistic. Intoxications might result from: (1) alteration in intestinal flora because of changed conditions, and bacteria thrive that produce septic toxic substances; (2) spread of bacterial processes up into the small intestine and (3) passing of normal intestinal bacteria into the blood from lowered resistance of epithelium, or lowered bactericidal power of blood-e.g., bacillus coli communis in the production of gall-stones, cystitis and phlebitis in influenza. In many instances it would be difficult, if not impossible, to draw a hard-and-fast line between intoxications and infections, because we could not tell whether the microbe had been able to enter the portal blood stream and had become bacteriolysed there, or whether the intestine had merely absorbed the toxins produced in the intestine. example of a disease that might be either an intoxication or an infection, they might take Hamilton's work on "louping or paralytic chorea in sheep, because it gave us a clue as to the line along which research would have to be carried out in man to establish the pathology of like conditions. Hunter had laid great stress on oral, gastric, and intestinal sepsis as the cause of pernicious anæmia. Rolleston explained the production of cirrhosis of the liver by the view that alcoholic excess led to a prolonged gastric catarrh, which, by lowering resistance, enabled toxic substances to be absorbed from the bowel. Hamilton's suggestion was that a microbe was absorbed from the intestine, bacteriolysed in the portal blood, and its liberated toxins anchored on to the liver substance. Chronic affections of the joints had been attributed to a chronic infection or intoxication,

and either the alimentary or the genito-urinary tract might be the "open door" by which the infective agent enters. The prevention and treatment of a case of proved intestinal intoxication was summarised as follows: (1) a simple diet, largely of milk; (2) ordinary regulation of the bowels without any drastic purgation; (3) naphthalene tetrachloride may be used as an intestinal antiseptic; (4) attention to septic conditions of the mouth; and (5) identification of the microbe responsible and the preparation of the appropriate vaccine.

Rebiews and Notices of Books.

4 System of Operative Surgery. By Various Authors. Edited by F. F. Burghard, M.S. Lond., F.R.C.S. Eng., Teacher of Operative Surgery in King's College, London; Surgeon to King's College Hospital; Senior Surgeon to the Children's Hospital, Paddington Green. In four vols. Vol. I. London: Henry Frowde, Oxford University Press; Hodder and Stoughton. 1909. Pp. 751. Price 36s. net per vol., or four vols. £6 6s. net to subscribers.

THOSE who are most conversant with the recent progress in operative surgery appreciate most the rapid advance that is made year by year, in fact, but very few years are required to render out of date a work on operative surgery which at its first appearance was fully abreast of the time. One of the most remarkable points in connexion with medera surgery is the great widening which it has undergone, so that it is barely possible now for one surgeon, however encyclopædic his knowledge, to give an adequate account of the present position of the subject. Therefore, we notice that there is an increasing tendency to issue systems of surgery in which the special knowledge possessed by various operators can be combined for the production of a work dealing with the whole science.

This volume commences with a chapter dealing with the principles and technique of wound treatment by Mr. C. B. Lockwood. The matters dealt with are the air infection of wounds, the arrangements of operating theatres, the sterilisation of instruments, dressings, and materials used in operation, the purification of the hands of the operator and his assistants, and the skin of the patient where the operation is to be performed. The drainage of wounds and the treatment of infected wounds are also considered. From other writings of Mr. Lockwood we know the exactitude with which he treats all the elements entering into an operation, and this chapter fully reflects the great care, both theoretical and practical, which he devotes to his operations. As he points out, the increasing attention paid to the minutize of disinfection has been followed by a gratifying diminution in the proportion of cases in which the slightest taint of sepsis has been found. The greater the experience of the assistants, the greater the probability of rigid asepsis, but in hospitals, as Mr. Lockwood mentions, house surgeons and dressers are only appointed for limited periods, and as a result of this their terms of office come to an end at a time when they are beginning to be fully efficient. This system doubtless tends to a slight increase in the percentage of sepsis, but its educational value is immense, while it leads to the sending out into the world of large numbers of highly trained men. We concur in Mr. Lockwood's opinion that as a result of the present system of surgical education the inhabitants of the British Isles have at their disposal one of the best medical services that exist. As to the methods dealt with in this chapter there is little to say and we agree with almost every word which is written. Differences of opinion, no doubt, will exist on some of the details of the methods of sterilisation, but those who follow the teaching laid down here cannot go wrong.

A valuable section is that dealing with the methods of

local analgesia; it is written by Captain J. W. H. Houghton, R.A.M.C. He mentious that his article is little more than a full abstract of three papers by Mr. A. E. Barker, but that fact in no wise detracts from its value. The first chapter of the section deals with infiltration and regional analyssis. He prefers for this purpose a solution of beta eucaine with sodium chloride and adrenalin chloride, the beta eucaine being of the strength of 1 in 500 and the adrenalin chloride being of the strength of 1 in 200,000. We agree that this solution is extremely satisfactory. Spinal analgesia is also described, and the author favours stovaine, employing a solution containing 5 per cent. stovaine and 5 per cent. glucose. He attributes the distressing headache which occurs in some 15 to 20 per cent. of the cases to disturbance of the patient during the operation, for he finds that those patients whose heads are sufficiently raised, and whose position is unaltered after the injection, appear to escape all but the most trifling by-effects.

The editor himself has undertaken the section on amputations, and in nearly 200 pages he has supplied an excellent account of this important branch of surgery. The illustrations are especially good and should prove useful in elucidating the text. Detailed criticism would here again, as in the technique of asepsis, resolve itself usually into questions of opinion, but we think it would have been well in the description of Syme's amputation to lay more stress on the great superiority of dissecting the heel flap from above rather than from below in the way it was described by Syme himself. Moreover, we cannot agree that the functional results of Pirogoff's amputation are not so uniformly good as those after Syme's amputation. The operation is not improved by dissecting any heel flap as described in the text, and surely the author is in error in saying that it is difficult to secure bony union; fixation of the portion of os calcis by a silk stitch is useful in ensuring union of the bones. We fully agree with his praise of the Stokes-Gritti amputation, and consider that it is not nearly so frequently employed as it deserves.

Mr. Burghard is also responsible for the section on blood-vessels and lymphatics, and his account of the suture of blood-vessels is quite up to date, as is also his description of Matas's operation, but we feel inclined to protest against the name "endo-aneurysmorrhaphy" which he applies to it. This account is illustrated with some diagrams taken from Matas's paper and should assist in popularising the operation in this country. The ligatures of the arteries in various parts of the body are described, and he includes a chapter on the ligature of the abdominal aorta. We appreciate the difficulty of prophesying as to the domain of surgery in the future, but we doubt very much if ligature of the abdominal aorta will ever take its place amongst the recognised operations of surgery.

The section dealing with operations on nerves, also from the pen of Mr. Burghard, represents the modern teaching. The sections dealing with operations upon muscles, tendons, and bursæ contain a very good account of these important subjects, and especially good is that portion treating of tendon transplantation. The operations connected with bones and joints have been divided into two parts, and only those performed for non-tuberculous affections appear in this volume. In discussing the vexed question as to the frequency with which simple fractures should be dealt with by operation Mr. Burghard steers a middle course between those who hold that operation is never needed in simple fracture except for faulty union or non-union, and those who advocate early operative interference in all cases where a skiagram shows that exact apposition of fragments cannot be effected and maintained.

Plastic surgery has been very satisfactorily dealt with by Mr. T. P. Legg, and though it has not been possible to include a full account of this important branch of surgery within the 80 pages allotted to him, we are interested to see that the chief methods are very adequately described, quite sufficiently fully to enable a surgeon to undertake them. The account is greatly assisted by the numerous valuable illustrations with which it is supplied, some of which represent cases which have been under Mr. Legg's own care, and show the devices he adopted in order to secure good results. Success in plastic surgery depends more on the skill and adaptability of the individual surgeon than on the special method employed.

Judging of this new system of operative surgery by the first volume which has reached us we need have no hesitation in stating that Mr. Burghard has been very successful both in the choice of his contributors and in the substance of their contributions.

The Relation of Medicine to Philosophy. By R. O. MOON, M.A., M.D. Oxon., F.R.C.P. Lond. London: Longmans, Green, and Co. 1909. Pp. 221. Price 4s. 6d. net.

Dr. Moon has not attempted the impossible task of trying to treat exhaustively the wide subject of the Relation of Medicine to Philosophy within the compass of 221 octavo pages, and it might have been well to indicate on the title page the limitatons which he has set himself. His book is a modest and simply written collection of statements about medicine and philosophy throughout the ages, chosen so as to show, to use his own words, "how intimately medicine has been bound up with the current thought and philosophy of the day; how medicine no more than art can work away by itself, uninfluenced by the intellectual milieu in which it finds itself." Until some 300 years ago philosophy practically included all knowledge, and without going back so far as Aristotle it is enough to mention the names of Descartes, of Newton, and at a somewhat later date of Kant, and of Young as instances of master minds. So Plato considered that the philosopher should be "synoptic"—i.e., a man who insists on seeing things together. Dr. Moon commences by considering the pre- and post-Hippocratic schools of medicine, and then passes on to Galen, whose ideas, together with those of Aristotle, dominated medical and philosophical thought practically up to the Renaissance. Galen, following Aristotle, was a firm believer in the doctrine of final causes, a belief which, it will be remembered, Lucretius so earnestly denied as regards the bodily organs, as where in Book IV., 833, he says:---

> "Nil ideo quoniam natumat in corpore ut uti Possemus, sed quod natumat id procreat usum."

"Since nothing was born in the body that we might use it but that which is born begets for itself a use" (Munro).

Dr. Moon opens his fourth chapter with the statement that there remains one cause of the general decadence of medicine after the death of Galen for discussion, which by many has been regarded as the most important of all—namely, the rise of Christianity. The title of this chapter is "The Influence of Early Christianity on Medicine," but Dr. Moon has grasped the fact that the common attribution of the sterility and mysticism of the medicine of the time was due to the great power of Orientalism in the early centuries of the Christian era. It was no part of Christianity proper to consider the body an evil worthless thing, that mistaken idea was a part of Persian Dualism. The Christian, considering that his body was the temple of the Holy Ghost, was led to temperance and clean

living, while the notion of the brotherhood of all men induced the care for the sick, which that astute ruler, the Emperor Julian, saw to be one of the strongest points in favour of the despised religion. Dr. Moon gives all credit to the early Christians for their zeal in this direction and instances the organisation known as Parabolani, mentioning the derivation of the title from $\pi\alpha\rho\alpha\beta\lambda\lambda\epsilon\sigma\theta\alpha\iota$ ("to throw oneself into danger"). Many years before the Christian era a high-souled pagan had enshrined in immortal verse the nobility of nature evident in tending the sick. In his description of the great plague at Athens Lucretius tells how many of those who stayed to nurse the sick caught the infection, and he says, "Optimus hoc leti genus ergo quisque subibat" ("In this way many of the best died"). This was the spirit taught by Christ, and medicine could have had no more direct advocacy.

The rise of the Arabian domination is dealt with in Chapter V., and then follows an account of the various influences affecting medicine in the Middle Ages. As a rule the influence of Aristotle dominated all thought, and even a fairly free thinking philosopher such as Peter of Abano commenced a medical work by stating that medical questions might be treated according to the four causes. Dr. Moon gives much credit to that remarkable man the Emperor Frederick II., for refusing to admit any one to practise in the kingdom of Naples before having passed an examination by the Medical College of Salerno. The Emperor showed his desire for knowledge in curious ways. Salimbene (1221-1288) mentions in his chronicle a singularly brutal experiment of Frederick. "He fed two men most excellently at dinner, one of whom he sent forthwith to sleep, and the other to hunt; and that same evening he caused them to be disembowelled in his presence, wishing to know which had digested the better: and it was judged by the physicians in favour of him who had slept." The horror of the proceeding was not obvious to a thirteenth century autocrat, and must not be allowed to detract from his merits as the author of medical registration in his kingdom.

The Middle Ages passed away and the Renaissance dawned, an era which led to vast improvements in medical science owing to the revival of the study of human anatomy. We say revival, for although Galen's anatomy was founded on the dissection of apes, Mondino and others in the thirteenth century had dissected human bodies in a perfunctory manner. Vesalius upset many of the Galenic statements by his researches, and in fact the whole spirit of the age was one which favoured inquiry by the adoption of the belief that a thing was not necessarily right because someone had said so. We make no attempt to follow Dr. Moon through his account of medical and philosophical progress in the seventeenth, eighteenth, and nineteenth centuries, but we may add that he gives a short précis of the various movements and schools of thought. As an introduction to a subject of vast interest to those of the medical profession who have leisure in the midst of their daily toil to study one phase of the history of their profession we can recommend Dr. Moon's primer.

We are quite in accord with him in wishing for the time when medicine in all her several departments might be brought to a focus, just as Wagner endeavoured to bring into one whole music, poetry, painting, and dancing. Medicine "brought to such a focus as to subserve the purpose of a sane and rational life," says Dr. Moon, should now work hand in hand with philosophy, when philosophy in her turn will take from medicine all that is saved through the ages from ignorance and chaos, and "gather them up into one vast generalised truth which will at length enable men to lead the lives of intellectual and moral beings."

LIBRARY TABLE.

Formulaire, Consultations Médicales et Chirurgicales. (Medical and Surgical Formulary.) Par M. G. LEMOINE, Professeur de Clinique Médicale à la Faculté de Médecine de Lille; et M. E. GERARD, Professeur de Pharmacie à la Faculté de Médecine et de Pharmacie de Lille; avec la collaboration de M. J. VANVERTS, Chirurgien des Hôpitaux de Lille. Quatrième édition, conforme au nouveau codex 1908. Paris: Vigot Frères. 1909. Pp. 916. Price 7 francs.—This volume is divided into two parts, in the former of which we find a list of drugs and chemical substances arranged alphabetically, and under each heading is given an account of the physical and chemical properties of the substance and of its therapeutic action and use, and also a description of the way it may be employed. most cases a few prescriptions follow containing drug. A chapter on Organo-therapy follows and a useful list of incompatibles is also given. The second portion of the work contains an alphabetical list of diseases and symptoms, and under each heading is given a very brief description of the symptoms, with an account of the general hygienic management of the disease, followed by a more elaborate description of the usual treatment. It is obvious that in a volume of this size we must not look for a very full account of the treatment of disease, but for its size it contains a very great deal. The treatments indicated are reasonable and they may offer useful suggestions in cases of doubt, and the prescriptions supplied are, on the whole, well designed. An account of the principal mineral waters both in France and elsewhere is included. The principal health resorts are also briefly described. The book will be likely to prove of great practical service to any medical man who can read French. We do not know of any work in English which exactly represents it.

Minor Gynæcology. By V. ZACHARY COPE, B.A., M.D., M.S. Lond. With 11 full-page photographs and 30 illustrations in the text. London: John Lane. 1909. Pp. 274. Price 5s. net.—The author has written this work for the purpose of dealing with those aspects of minor gynæcology which are of most direct value to the practitioner; for this reason special stress has been laid on diagnosis and treatment, while only those operations and procedures are described which are usually undertaken by the family practitioner. At the same time care has been taken to indicate the occasions on which the services of the gynæcologist are likely to be required. The various chapters are devoted partly to a consideration of the affections of the different pelvic organs and partly to a description of the meaning of different symptoms—thus, for example, there are chapters on menstrual disorders and pathological uterine bleeding—and the author has included several sections on points not usually Thus, he touched upon in works of this description. devotes a chapter to the nervous system in relation to, women's diseases and one to medico-legal and medico-ethical points in gynæcology. These are of considerable value since it is more especially the gynæcologist in the practice of his specialty, or the general practitioner undertaking such cases, who is likely to require advice on questions of this kind. The important legal considerations involved often in the examination of single women by the use of the sound and the possibility of women seeking medical advice in the hope of having a sound passed, and so abortion being procured, are dealt with, as are also the legal points involved in the performance of operations, and the medico-ethical relations of syphilis and gonorrhoea. No doubt there is a place for an elementary work of this kind and the author is to be congratulated on the clear and orderly manner in which he has presented the chief facts of the diseases affecting the female pelvic organs. It is a pity he has not taken a little more trouble about the spelling of

the names of the authorities he quotes; thus we find M'Cann for McCann, Schultz for Schultze, M'Naughton Jones for Macnaughton-Jones, while the statement that the fundus of the uterus is normally on a level with the plane of the pelvic inlet is incorrect.

A Guide to the Feeding of the Infant during the First Year. By J. W. SIMPSON, M.D. Edin., F.R.C.P. Edin., Assistant Physician, Sick Children's Hospital, Edinburgh. London: Simpkin, Marshall, and Co. Edinburgh: James Thin. Pp. 80.—This little book contains a careful discussion of the various methods of feeding an infant during the first year, written in simple language and stripped of needless technicalities. It is divided into two parts, the first dealing with breast-feeding, the second with artificial methods of dieting. The necessity for regular feeding and for strict attention to details is forcibly urged. The contra-indications to breast-feeding are given, and the subject of weaning is discussed in detail. Various methods of artificial feeding are described, with full directions as to the preparation of the food and the manner of giving it. Dr. Simpson rightly inveighs against the use of patent foods. He mentions various difficult conditions as regards feeding, and gives simple hints in regard to the domestic management of conditions such as vomiting, colic, diarrhœa, and constipation. We have nothing but praise for this book, which should be useful alike to young practitioners and to mothers, for it is practical and explicit in its recommendations.

How to Become a Nurse: the Nursing Profession, How and Where to Train. Edited by Sir Henry Burdett, K.C.B. London: Scientific Press. Pp. 463. Price 2s.—This guide may be thoroughly recommended to young women contemplating a nurse's career. There is an introductory chapter on advice to women desirous of becoming nurses, which is simple, sound, and discreet; chapters on the chief branches of nursing and the remuneration which may be expected; general information as to training schools; and a very full directory of institutions for training and employment of nurses. This directory fills nearly 400 pages, and is well revised and up to date. There is a chapter on the working of the Central Midwives Board, in which Sir Henry Burdett shows a wise and non-committal attitude in his valuation of the working of the Act.

JOURNALS AND MAGAZINES.

Archives of Neurology and Psychiatry. From the Pathological Laboratory of the London County Asylums, Claybury, Essex. Vol. IV. Edited by F. W. MOTT, M.D. Lond., F.R.S., &c. London: P. S. King and Son. Pp. 330.—This volume of the Archives opens with an interesting article by Dr. Henry Mandsley on the subject of "A Mental Hospital-Its Aims and Uses." The establishment of such a hospital is advocated with the author's usual force and clearness. "Exaggerated apprehensions of danger and the common notion of insanity as a disgrace to be concealed or put out of sight, rather than a disease to be soon and wisely dealt with, are still responsible for much neglect of early attention and for many impediments in the way of its proper care and treatment. If a mental hospital, in close touch with the general hospitals and medical schools, helps to instil the notion of disease and to dispel unwarranted prejudices it will not have been built in vain." It is with regret that we notice that time passes by and little or nothing seems to be done by those entrusted with the management of Dr. Maudsley's munificent gift dedicated to the foundation of such a mental hospital in London. For a large proportion of the articles in this volume Dr. Mott is himself responsible, and of these three are given to describing the effects of syphilis upon the nervous system. The first of these consists of the Morison Lectures delivered at the beginning of this year before the Royal College of Physicians of Edinburgh, which contain an admirable résumé of our present knowledge of the subject. In another article Dr. J. P. Candler as a result of a research of a year's duration comes to the conclusion that the assumption that a particular group of diphtheroid organisms acts as the specific factor in the production of general paralysis is unwarranted and has not yet been substantiated by any published record. A particularly interesting article is that of Dr. C. U. Ariens Kappers of Amsterdam upon the Phylogenesis of the Palseocortex and Archi-cortex compared with the Evolution of the Visual Neo-cortex. Comparing his work with that of Dr. Mott, the author is of opinion that we find nearly the same principles as well in the progressive development of the palæo- and archi-cortex as in the progressive evolution of the visual neo-cortex. The volume contains many excellent illustrations.

The Dublin Journal of Medical Science.—The October issue of this journal is an "Educational Number" in which some 30 pages are devoted to a consideration of medical education and examinations in Ireland. Dr. Robert J. Rowlette contributes a Pathological Report of the Rotunda Hospital for the year ending Oct. 31st, 1908, and Dr. G. Jameson Johnston reports a case of retro-peritoneal sarcoma in a youth aged 21 years. Surgeon-Colonel D. Edgar Flinn gives an account of an outbreak of enteric fever at Clontarf in which the mode of dissemination was difficult to trace, but was in all probability by means of infected milk.

West London Medical Journal.—In the October number is published a very interesting and useful presidential address by Dr. Nev'lle Wood on Spa Treatment, an abstract of which appeared in the last issue of The Lancet. Mr. C. B. Keetley contributes the first instalment of some historical notes on the West London Hospital and people connected with it, among whom are noted Mr. Teevan, Dr. Thorowgood, Sir Alfred Cooper, Mr. J. Astley Bloxam, and Mr. Bowater J. Vernon. Notes of a case of Double Pneumonia followed by Empyema and Peripheral Neuritis are given by Mr. H. W. Chambers; and a case of Perforating Ulcer, which was the first symptom of tabes dorsalis, by Mr. D. C. L. Fitzwilliams.

The Midland Medical Journal.—The original matter in the October number of this journal consists in an abstract of a post-graduate lecture by Dr. Leonard G. C. Mackey on Bacteriology in the Diagnosis and Treatment of Disease. It gives a short account of recent work on opsonins and vaccines, and insists on the importance of a bacteriological examination of the blood to ascertain the actual germ at work in every case.

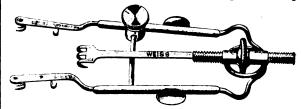

The Archives of the Roentgen Ray continues to occupy the foremost place among those papers bearing on its subject and published in the English language. Its prominent position in the X ray world is almost entirely due to the energy and enthusiasm of the editor, Mr. W. Deane Butcher. It is also due to the excellent form in which the paper is issued to its readers; and until recently, at least, no better reproductions of skiagrams were to be found anywhere. In the October number, which is now before us, we observe that the illustrations are being reproduced by an apparently different process from that in use heretofore, and we take the liberty of saying that the change is not for the better. We trust that it is due to a temporary arrangement, as these Archives are worth the best form that can be given them. In the text we find an article from the editor's pen bearing upon the risks attending Roentgen epilation. He comments upon the singular unanimity among experts in this country as to the harmlessness of the procedure, although many of the leading radiologists abroad, where X ray therapeutics are more extensively practised than in

this country, are by no means so sure about the The plea for caution is justified until further experience has been gained. An article follows by Dr. Walter of Hamburg on the Measurement of the Intensity of Roentgen Irradiations. In these days, when most radiologists pin their faith to the Sabouraud pastille, it is interesting to note that in the opinion of so great a worker as Dr. Walter "the most accurate and the most universally applicable means of dosage hitherto available is the simultaneous use of the milliampèremeter for the quantity and some scale of hardness for the quality." Dr. Alban Köhler of Wiesbaden describes a method of Deep Irradiation without Permanent Injury to the Skin. To attain this end he uses an X ray tube so constructed that the rays come from a comparatively large surface on the anticathode instead of the usual point, the radiating surface being from 1 to 1½ centimetres in diameter. A filter of leather is placed on the skin, and upon this a metal gauze made of No. 36 iron wire and 14 meshes to the inch. The X ray tube is adjusted a few centimetres above the gauze. "By this device we obtain a perfectly uniform irradiation at a certain definite depth, as uniform as if there were no metal network between the focus tube and the irradiated tissue." In this way he can give ten times the erythema dose, and while the exposed cutaneous cells are destroyed yet each little area so destroyed is surrounded by healthy uninjured tissue and healing rapidly follows. The idea is a novel one, and should be fully investigated. Dr. A. Béclère of Paris gives his experiences in the Radio-therapeutic Treatment of Tumours of the Hypophysis, Gigantism, and Acromegaly, in which he appears to have had some success. Mr. T. G. Beckett of Melbourne describes an ingenious method for regeneration of X ray tubes which he has found quite satisfactory for over three years. Like one recently brought forward by Bauer, it works by allowing a small quantity of air to leak in through a fine fissure or fissures which are normally covered by mercury. The arrangement is easily made, is efficient, and in a dry climate ought to be quite satisfactory. The possibility of water vapour getting in must be reckoned with in a climate like that of the British Isles, as it is known that such is prejudicial to the best work. The rest of the number is taken up with reports of societies, reviews, and an abstract of current literature.

Rew Inbentions.

A RETRACTOR FOR USE IN EXCISION OF THE LACRYMAL SAC.

Some form of retractor is almost a necessity in performing Firstly, to the operation of excision of the lacrymal sac. open out the incision which is awkwardly situated in a narrow place betwixt the inner canthus of the lids and the side of the nose; and secondly, because efficient traction on the tissues provides the best means of checking bleeding. At present Müller's and Axenfeld's tractors are the most generally used. The instrument shown in the illustration combines the actions of these two forms of retractors. The frame is that of Müller and it is no larger than his neat model. But by an alteration of the prongs at the extremity of the laterally-acting blades and the addition of a claw (something like an old-fashioned "back scratcher"), which can be drawn back by the milled nut at the spring end of the frame, this retractor will exert the powerful tractor action of Axenfeld's instrument and yet leave the upper end of the site of the operation free. In inserting the new retractor the instrument should be first closed, the blades approximated, and locked by a turn of the side check-screw, and the long claw pushed home to just behind the side prongs of the lateral blades. The claws are inserted into the wound just as in using Müller's instrument. Now the side check-screw is released and the blades, being forced apart by the spring of the frame, stretch the incision laterally; the side check-screw should now be firmly locked. The blades are then gently pressed into the wound by one finger and the milled nut at the spring end of the frame turned so as to draw back the long claw; the front claws on the blades are pivoted and so shaped that they oppose the backward drag of the long

claw, so that the incision is stretched tight. The field of the operation is well exposed and the traction exerted on all sides of the wounds acts as a most efficient hæmostat, yet the important upper limit of the wound is left quite free of any obstruction that would hinder the work of the surgeon.

The instrument is made in excellent fashion by Messrs.

N. BISHOP HARMAN.

BRITISH MEDICAL BENEVOLENT FUND GUILD.

A MEETING was held at the house of Sir John Tweedy, 100, Harley-street, on Thursday, Oct. 28th, for the purpose of inaugurating a Guild in connexion with the British Medical Benevolent Fund. The object of the Guild is to make the fund more widely known and to obtain additional support for it, especially from women, and to supplement its work by giving help and practical sympathy to the beneficiaries of a more personal character than is possible for the parent fund. Sir John Tweedy presided, and among those present were

Sir John Tweedy presided, and among those present were Lady Tweedy, Sir William and Lady Church, Lady Barlow, Mrs. Butlin, Mrs. Scharlieb, Mrs. Rose Bradford, Lady Fripp, Mrs. West, Mrs. Liveing, Mrs. Godlee, Mrs. Croker, Lady Critchett, Dowager Lady Broadbent, Lady Broadbent, Miss Broadbent, and Dr. S. West.

Sir John Tweedy said that there was appalling distress among the poorer members of the medical profession, and without some such help as this Fund had been able to give hundreds of wives, daughters, and sons of practitioners would have had to face extreme poverty and destitution.

Lady TWEEDY gave particulars of cases of distress among the families of many members of the medical profession, and urged that in the new Guild ladies should be the missionaries of the Benevolent Fund. The Guild proposed to visit and take personal interest in the cases recommended by the executive committee of the Fund, to make gifts of clothing and other necessaries, and to do such other work as might from time to time seem desirable and be approved by the executive committee of the Fund.

Dr. West said that while the Fund would deal with money the Guild would give not money but money's worth. State aid sapped private charity, and many people had begun to feel that as they were compelled to contribute to old-age pensions they would now give their voluntary contributions not to the so-called working class, for which so much was already done, but to the poor of their own class. There could be no worthier object than the relief of the poor members of the medical profession, and the Guild appealed for support not to the medical profession only but to the public at large, upon whom it has such strong claims.

Dr. WEST then proposed a motion that such a Guild should be established. This was seconded by Lady CHURCH and carried unanimously.

The following officers
Dowager Lady Broadbent.
Chairman: Lady Tweedy.
Were appointed:—President:
Treasurer: Dr. Mary Thorne.
Honorary Auditor: Mr. Knox,
with a council and various committees.

The Guild was to consist of members who paid not less than 10s. 6d. annually and associates who paid not less than 2s. 6d. annually.

Subscriptions and donations to the Guild may be sent to Lady Tweedy, 100, Harley-street, London, W., and to Dr. Mary Thorne, 148, Harley-street, London, W. Paroels of clothing, &c., may be sent to 11, Chandos-street, Cavendish-square. Letters and communications should be addressed to the Secretary, 100, Harley-street, London, W.

LANCET. THE

LONDON: SATURDAY, NOVEMBER 6, 1909.

The Relation of the Medical Practitioner to the Practice of "Christian Science."

THE latest death due to "Christian Science," which has attracted attention owing to the publicity accorded to the inquest in the newspapers, is that of Colonel CHARLES ALEXANDER, a retired military officer. It was stated before the coroner that Colonel ALEXANDER, who was only 55 years of age, had enjoyed robust health, but had recently had an attack of influenza and a hunting accident. Apparently his practice of "Ohristian Science," which cult he professed, did not result in a very complete recovery from the influenza, but a more severe test of his faith and of the self-confidence of the "healer" occurred when he developed variouse ulcers on his legs. These developed in due course to a serious extent and it was stated at the inquest that they were washed but that no further treatment was accorded to them. On Monday, Oct. 25th, they were evidently worse than they had been before and his general condition was bad. Mrs. CAROLINE PAULINE MACDONALD, a "Christian Science healer." residing in Drayton-gardens, was consequently summoned by the patient's wife, he having refused to see a medical man. It is fair to both Mrs. ALEXANDER and Mrs. MACDONALD to say that according to their evidence the patient refused to have medical aid. Mrs. MACDONALD, however, appears to have been sufficiently aware of the serious condition in which Colonel ALEXANDER was and of the responsibility which might attach to herself in the case of his death, to advise the summoning of a medical man with the intention, however, that he should make a diagnosis of the case for the satisfaction of the relatives but should not administer treatment. The patient approved of her sending on these grounds for a medical man whom she knew, but this gentleman refused to attend in the circumstances. Monday, therefore, and Tuesday passed without the patient, whose perilous condition was obvious, receiving medical advice. On Wednesday, Oct. 27th, a medical man was summoned, who, according to his evidence, found the patient suffering from varicose veins and ulcers. He suspected that gangrene had set in and he formed the opinion that whatever steps might be taken it was then hopeless to attempt to save life. He was not asked to attend the patient or to give any treatment, but only to diagnose the case. In the evening he learnt that Colonel ALEXANDER was dead. Dr. B. H. SPILSBURY, who made a post-mortem examination, stated, as the result of it, that death was due to syncope following acute blood poisoning set up by the ulcers. To this he added, in reply to the coroner, that taken in reasonable time such ulcers should have been amenable to medical treatment, and accelerated death, a view which the jury adopted in their verdict, but rightly laying the responsibility of refusing medical aid upon the deceased himself.

So far as "Christian Science" is concerned this last case adds to its tragic chronicle the record of the unnecessary death of a man in the prime of life. Colonel ALEXANDER contributed fully to bring about his own untimely end, but Mrs. EDDY, the high priestess of the cult, and Mrs. MACDONALD, who allowed herself to pose as a "healer" of that which she had no power to heal, played their parts in the tragedy, as did the whole host of other persons with whose folly the deceased associated himself. And as there is no ground for hope that this case will be the last of its kind, the position of medical men summoned to make a diagnosis in such circumstances may be usefully considered. What the motive for such a summons may have been in this particular case is not quite clear. Something was said at the inquest about the probable feelings and views of relatives who were not "Christian Scientists," and perhaps consideration of such family feeling had its influence, but it is safe to presume that on occasions of this kind the question of the procuring of a medical certificate of the cause of death is not absent from the mind of the "healer" whose patient, instead of being healed, is apparently moribund. Two medical men in succession were invited to attend Colonel ALEXANDER, the first refused, and the second consented to go. The one who refused, who was claimed by Mrs. MACDONALD as an acquaintance, probably knew better what to expect than his colleague, and none can blame him for declining to take part as an ineffectual onlooker at a death-bed, with the almost certain consequence of attendance later at an inquest. On the other hand, we do not see that the medical practitioner who obeyed the summons could act in any other way than he did. If we weigh the considerations which should influence the medical practitioner who receives such an invitation, and if we assume that he has knowledge of the fact that a "Christian Science healer" will be present at the bedside and that there is no intention on the part of the patient or of the relatives to allow medical intervention, we must still remember that in the face of imminent death opinions and intentions may waver, and that it is the medical man's duty to save life where it is in his power to do so. In the circumstances imagined he may find a patient in such a state that it will be his duty to say to a wife, to a husband, or to a parent, "Here is a life that is being sacrificed; without medical aid death must come within a short period, but it may be averted." The alternatives so offered, not, perhaps, in the precise terms we have used, but with unmistakeable clearness and with gentle but firm insistence, would be a severe test of the faith of the "Christian Scientist," and the infatuation, which so often has allowed near and dear relatives to die without remonstrance or effort to save them, might relax. We may picture the case, moreover, as that of a patient who, in the early stages of disease, declined medical aid, but who, when that aid is at hand, lies unconscious and unable to feel or to express either dissent or assent. It would be a heavy responsibility that would then rest on those around him, and we believe that it would be the duty of the medical man to that in his opinion the absence of such treatment had lay its full weight upon their shoulders. His first effort,

however, would be to make those representations which would be most likely to procure for the patient medical aid and nursing with a view of prolonging life or of alleviating suffering.

We have referred to the possibility of a medical man being called in by "Christian Scientists" with the intention that he shall facilitate burial by certifying the cause of death, although he has not been allowed to treat the patient. In such circumstances it may, perhaps, be within his discretion either to refuse a certificate or to sign one naming the illness and adding that death was accelerated by neglect. We do not, however, recommend the latter course, as we are of the opinion that the mere opportunity for diagnosis cannot reasonably be regarded as attendance during the last illness within the meaning of the Births and Deaths Registration Act, 1874, and because the refusal of the certificate is more in accordance with the present practice. The result is that the attention of the coroner is drawn to a case in which deliberate neglect to procure medical aid has apparently assisted "natural causes," and an inquest is rightly held in order that all the facts connected with such a death may be ascertained.

Traumatic Late Apoplexy.

WHEN a man dies with cerebral symptoms soon after an injury to the head little doubt can be felt as to the causal connexion between the injury and the fatal issue, though even here it is possible that nothing more than a coincidence has occurred. When, however, a definite interval of apparent health, complete or almost complete, has intervened between the infliction of the injury and the occurrence of those symptoms, and the symptoms pass rapidly on to death, much doubt must arise as to whether the injury really was the cause of death. The old common law used to recognise a limit of a year and a day; if this period of time elapsed between the infliction of an injury and the death, the doer of the injury was not held accountable for the fatal result that followed. Whether, however, such a principle still holds in English law we leave the lawyers to decide. Cases have, however, from time to time been published where after the infliction of an injury of the head a very definite interval of almost complete health has followed, and has lasted for several weeks or even months, but at last the patient has died with symptoms pointing to a cerebral lesion, while at the necropsy sufficient evidence has been found to lead the observers to the conclusion that the original injury was really the ultimate cause of death. The whole subject is of great interest both surgically and legally, and may well repay a little consideration.

In 1878 DURET reported a series of experiments which he had made with regard to the effects on the brain of severe blows on the skull. These experiments were followed by lacerations and foci of softening in the neighbourhood of the lateral ventricles, of the aqueduct of Sylvius, and of the fourth ventricle. There was no doubt about the lesions produced, but there was less certainty about the correct explanation of their mode of production. Durer ascribed them to the alteration in shape of the lateral ventricles by which the cerebro-spinal fluid was, or might be, driven and then the child became more drowsy, but about five weeks

violently from them into the third and fourth ventricles, and where these channels are the most narrow there the lesions are found, because, he considered, that there the pressure would be greatest. In 1891 BOLLINGER of Munich published four cases in which death occurred at a late period after an injury to the head. The injury did not lead to unconsciousness, and during the latent period the patients were able to follow more or less satisfactorily their usual lives, and in each of the cases cerebral lesions were found corresponding in part to those described by DURET. For these cases BOLLINGER invented the title of "Traumatic Late Apoplexy." Cases such as these certainly do occur, though they are rare, and the name has been applied especially to those in which there is found a subdural hæmorrhage resulting from the brain lesion, and Bowen has collected 72 instances of "Traumatic Subdural Hæmorrhage." Bollinger employed Durer's experiments and theories to explain the cases he described. The main points on which BOLLINGER insisted were the absence of loss of consciousness, the capability to follow the ordinary mode of life during the latent period, which in his cases lasted from 12 to 52 days, and, lastly, the post-mortem findings. These explanations failed to satisfy STADELMANN, who, in 1893, pointed out that softening foci in the brain are frequently spontaneous in men who are getting on in years. And he urged that it is very dangerous to accept the causal relation between trauma and cerebral softening when a long interval has occurred between them. He was therefore led to lay down three criteria. applicable to cases of traumatic late apoplexy. Before the injury occurred no sign of ill-health should have been present, no alteration in the blood-vessels should have existed, syphilis, nephritis, alcohol, and heart disease must have been excluded, and cases occurring in the old must be left out of consideration because in advanced age arterio-sclerosis spontaneously caused is very common. He thought it advisable also to insist that the injury must have been great, and lastly, that the signs of disease must have developed within a short time and under observation. Several other papers have appeared on the subject, and much of the discussion which has taken place has been based rather on theoretical considerations than on the direct observation of cases.

We publish in this issue of THE LANCET an apposite case. For the full particulars we refer our readers to Dr. A. H. MILLER'S paper. Here we will merely summarise A child in perfect health was struck on the the facts. head with a stone held in the hand of another child. No unconsciousness followed though there seems to have been a little dizziness. She cried a little but she was able to walk home without assistance. No skin lesion resulted, but when she reached home she seemed to be a little drowsy and wished to lie down. For the next fortnight she was fairly well, though she showed some fretfulness and complained of headache, but she was able to go to school for two half days. The first definite symptom that appeared was slight drooping of the right upper lid, which was noticed four days after the accident. Ultimately the right third nerve became completely paralysed

after the accident she grew much brighter and was allowed to get up. Six weeks after the accident the right fourth nerve was also completely paralysed, and she was very drowsy. A week later suddenly she became semi-conscious and died 12 hours later. At the necropsy a large hæmorrhage was found covering both cerebral hemispheres, and on the under surface of the right temporal lobe was a small irregular cavity filled with blood formed by the breaking down of softened brain substance. It is clear that this case fulfils most of the conditions laid down by STADELMANN, though the initial violence was not great. But the site of the softening bore no relation to the ventricle, though it corresponded to the antipodes of the site of injury, and Dr. MILLER is inclined to ascribe the lesion in the temporal lobe to the agency of cerebro-spinal fluid and not to "contre-coup." For, as he explains in his paper, he considers that the wave of cerebro-spinal fluid set in motion by the blow would distend the cisterna basalis and would spread over the inner and under surface of the right temporal lobe, rupturing the small vessels suspended in the cerebro-spinal fluid in the meshwork between the arachnoid and the pia mater, and these vessels being torn and blocked by clot, there would result a loss of the blood-supply of the cortex of the brain adjacent to them, giving rise to softening. We have been much interested by the explanations put forward by Dr. MILLER, and if they are sound they would doubtless serve to explain many cases of traums of the base of the brain which are usually ascribed to "contre-coup." More cases must be reported before any dogmatic statement can be made, and any similar good examples of the long interval which may elapse between the infliction of a comparatively slight head injury and the occurrence of a fatal result should be published. When fair health has existed in the interval between the injury and the death it is difficult to overestimate the importance from a medical and legal point of these cases. They offer points of great clinical and pathological difficulty and cause much conscientious hesitation on the part of those called upon to give expert evidence in a court of law. As far as the patients are concerned, also, the more widely our knowledge of such injuries extends the more chance will there be of lessening the difficulty of prognosis. It has well been said that no head injury is so slight that it can be safely neglected, nor so severe that it need be despaired of. We are indebted to Dr. MILLER for his valuable report of a rare condition in a form which is a definite addition to our knowledge.

The Work of the Association of Public Vaccinators.

THE annual meeting of the Association of Public Vaccinators of England and Wales, which was held at Liverpool on Oct. 29th, and whose proceedings are briefly reported in another column, marked the conclusion of the tenth year of the existence of a body which may well be congratulated on the vitality which it manifests and the position to which it has attained. The elaborate report of the secretary of the association, Mr. GREENWOOD, gives a minute survey of the work of the association during behalf of the urban boroughs, and Mr. A. MAUDE on

its ten years' existence, years throughout which a continual attempt has been made to discredit vaccination in the eyes of the people and of the legislature. We can think of no branch of work in the medical or in any other profession which has sustained such organised, continuous, and baseless attacks, and in spite of all the work of the public vaccinator has been throughout well and loyally performed. The sterling strength and sense of some of the officials at the Local Government Board have here been of great support, but we must not fail to realise the additional help to the cause of vaccination which the Association of Public Vaccinators has exercised. If full support had been given to the association by the majority of public vaccinators the danger to the public health which exists owing to the presence of so many unvaccinated persons in the country would be enormously minimised, and public vaccinators themselves might possibly be in the enjoyment of some fixed tenure of office, instead of being liable as they are now to dismissal at four weeks' notice by the board of guardians.

The medical profession has much to think of, but of that profession some 12½ per cent. in this country are public vaccinators, and it shows no great enterprise that the active work and financial support of the Association of Public Vaccinators should be left to a small hardworking minority. On this point Mr. GREENWOOD speaks in trenchant terms, and his strictures are of greater value in that he is not a medical man, but a solicitor of wide business experience, who views (for the secretary's report to the Council of the Association of Public Vaccinators is, we believe, entirely his personal work) with some astonishment the lack of unity in the medical profession. Mr. GREENWOOD is not the first person to have this feeling. In the report there will be found an historical survey of the work performed in ten years. The association was started to watch the interests of vaccination and vaccinators during the drafting of the Act of 1898. Its suggestions and recommendations were received in a generous manner by Mr. HENRY CHAPLIN, then President of the Local Government Board. A complete register of public vaccinators was made and has been since maintained. In 1901-02 local sub-secretaries or correspondents were appointed, one roughly representing each union, and an exhaustive report was compiled containing the opinions of the Council of the Association upon the administration and practice of vaccination and the changes desirable in it. The association, having the interests of its members before it, naturally opposed the principle of State payment for vaccination to other medical men than its members, but it must always be remembered that, as vaccination is in the hands of the medical profession as a whole, no untenable claim by the public vaccinators to a monopoly has been In 1903 came the cry from boards of put forward. guardians with regard to the expenses of house-to-house vaccination, with its attendant notices, reports, and reiteration of visits; and a Departmental Committee sat to investigate the question. Three witnesses were allowed to give evidence for the public vaccinators-viz., Dr. A. E. COPE representing London, Dr. A. DRURY on behalf of the rural districts of England and Wales. Their evidence covered 18 pages of the Blue-book, they answered 646 questions in the witness chair, and occupied that chair for the whole day. Returns on various points had been obtained from 800 public vaccinators, and these were sifted and tabulated by the witnesses and submitted in evidence. The report of the Departmental Committee was made in May, 1905, and in the same month the Association of Public Vaccinators, having appealed to the Local Government Board in vain for the issue of literature which should enlighten and instruct the public upon the law and practice of vaccination, proceeded to do that work itself. The association printed and published an excellent popular pamphlet, "The Truth about Vaccination," of which 75,000 copies were distributed before the close of the year. In May, 1907, however, the President of the Local Government Board issued an Order reducing the fees of all public vaccinators, though the action was not in accord with the recommendations of the Departmental Committee, which had also made suggestions to relieve public vaccinators from unnecessary and unpaid work. Mr. Burns has shown during his tenure of office great sympathy with medical aims and an enlightened conception of the claims of preventive medicine, and we do not think that he saw that by his Order many public vaccinators were handed over to the tender mercies of anti-vaccination guardians. There were certain facts, and unfortunately one or two scandals, which made the course taken by the President of the Local Government Board a probable one, but the results to some 3000 hard-working medical men could not have been foreseen by him. The work of the Association of Public Vaccinators has been rendered proportionately difficult by the existing condition of affairs.

An important memorial was offered to the President of the Local Government Board in May, 1908, and representations are still engaging the careful consideration of the Department, the question of the security of tenure of the office of public vaccinator especially pressing for settlement When Dr. DRURY of Halifax took office as President of the Association of Public Vaccinators in 1908 a new sphere of work was undertaken in the form of direct propaganda in favour of vaccination. Replies were made to the unscrupulous statements of the antivaccinationists in the public press; the President and other officials appeared at meetings to defend the principle of vaccination, and an excellent pamphlet on the "Prevention of Small-pox" was largely circulated. Some valuable suggestions for spreading a proper knowledge of the subject were also made by the secretary. In the first three years of its existence the numbers of the association rose from 340 to 970, and they have remained much at that level, but it is not to the credit of public vaccinators that this figure is below one-third of their number. The fact that the work of the association increases is shown by the mere details of the labour undertaken in its secretariat; the fact that the active members of the association have continued and increased the amount and scope of their work is proof that they, who are the best judges of the question, consider their work worth doing, for there is only one paid official; surely one-third of the public vaccinators should not be left to provide labour and finances for the rest of their fellows, especially as a graduated subscription is levied in proportion to the empluments of the subscribers.

Annotations.

"Ne quid nimis."

EPIDEMIC ABORTION IN CATTLE: A STUDY IN VETERINARY BACTERIOLOGY.

THE report of the Departmental Committee appointed in 1905, under the presidency of Professor (now Sir) John Macfadyean, to inquire into the causation of epizootic abortion in cattle has been issued recently, and confirms in a very complete manner the researches of Professor Bang on the same subject. Bang in 1897 had described as the causal organism of this condition a very small non-motile, non-Gram-staining bacillus which he found in the exudate bet een the fcetal membranes and the uterine mucous membrane, and also in the stomach and the blood of the fœtus. The report points out that even after several months of infection the disease may be localised to one spot of the uterus, and in one case even where there was a twin pregnancy one horn was considerably affected, while the other was apparently healthy. The bacillus was best found in the exudate around the fœtal membranes and here were seen small bacilli, oval or rod-shaped, sometimes lying singly but in many cases being markedly clumped. This clumping is attributed to the agglutinating action of the animals' serum, and it is one of the characteristics of the bacillus when grown on serum media. Bang had described the bacillus as growing in a shake culture only in a definite zone of the tube (from ½ to 2 centimetres below the surface), but the English cultures were found to grow best either on or just underneath the surface. The bacillus grew on all the ordinary media, but the agar-gelatin-serum medium which had been used by Bang was found the most favourable. Ordinary agar, on which Bang had failed to obtain cultures, was found to give good growths, although they took ten days or more to appear. On potato a growth was obtained very closely resembling that obtained with glanders. The organism only grew between 30° and 37° C. and it was destroyed by heating for ten minutes at 60°C. As regards the methods of spread of the disease some interesting facts come to light. The two natural modes of infection are by the vagina and by the mouth, and when animals were experimentally infected by these routes it was found that whereas by the vaginal method five gave positive results and three negative, when the animals were fed with virulent material three gave positive results and only one failed to become infected. This, then, would point to the food being a very important factor (if not the most important) in the spread of the disease. No opportunity occurred to test whether a clean cow could be infected by a bull which had recently served an infected cow. The committee succeeded in infecting all of eight cows by experimental intravenous inoculation, while three out of five became infected when large quantities of infective material were injected subcutaneously. While they are of the opinion that bovine abortion is essentially a disease of cattle and is not likely to spread to other animals, yet it was found possible to infect experimentally animals such as ewes, goats, bitches, and guinea-pigs. In the absence of an Order requiring the disease to be reported, it was impossible to obtain exact figures as to its prevalence, but the committee has established from bacteriological examinations that it was present on 55 farms in 36 counties in Great Britain, so that it must be common. The disease runs a chronic course, and there are no symptoms by which it may be recognised. The agglutination test was found to be untrustworthy. The subcutaneous injection of an "abortin" prepared from the basillus after the antenner

of tuberculin, however, has given promising results, as also has the "complement fixation" test of Bordet and Gengou. It was attempted to immunise non-pregnant animals by means of large doses of the living cultures of the abortion bacillus, but the results have been disappointing in the case of ewes with which most of the experiments were done. In the case of cattle, however, the two immunised animals tested both resisted successfully the intravenous inoculation of large quantities of infective material, while all of the non-immunised animals became infected. Treatment of infected cattle by means of vaccines also gave very promising results, two of the three animals treated being cured, while in one case the treatment failed. The details of the experiments are given in an appendix to the report signed by Sir John Macfadyean, who investigated the subject at the Royal Veterinary College, of which he is principal, and Mr. Stewart Stockman, chief veterinary officer to the Board of Agriculture, who had charge of the bacteriological investigations at the Board's laboratory and experimental farm. These observers are to be congratulated on having firmly established the causative agent of epidemic abortion in the herds of Great Britain, and their researches afford a foundation for measures which should eventually eradicate or diminish a disease of great importance to the agricultural community.

ALPINE MISADVENTURES DURING THE LAST TWELVEMONTH.

FROM Oct. 15th, 1908, to the same date of the present year, the deaths due to misadventure on the Alps (Swiss, French, and Italian) were no fewer than 84-a figure which seems to justify the Roman journalist in remarking that what Sir Leslie Stephen called the "playground of Europe' might more fitly be styled its "graveyard." The statistics from which this return is taken, compiled at Domodossola and just communicated to the press, set forth that the greatest number of casualties befel the Swiss and the Germans next in order were the English-speaking "Alpinisti," then the French, and finally the Italian. But if the last-named nationality figures lowest on the numerical side it takes highest place on the tragic, no misadventure of the twelvemonth equalling that of the three intrepid Milanese "peak-stormers," the Signori Sommaruga, Bompadre, and Castelnuovo, whose fate seems to have been identical with that of Signor Marinelli Damiano, who, with the two guides Imseng and Pedrazzini, was engulfed past all recovery in one of the crevasses of the Monte Rosa. Search parties, strong in numbers and equipment, succeeding each other at short intervals, have in both cases had to return from the quest baffled and disappointed. Next to the Monte Ross, on one of the many lichen-frescoed façades of which might be inscribed the warning-

"Mitte sectari Rom quo locorum Sera moretur!"

the Ragno-kulm, in the Valle Vigezzo, seems to have been the deadliest lure, drawing to his destruction the Genoese Signor Enrico Cavallo, just when the pious care of their bereaved parents had renewed upon its rocks the tablet recording the tragic end of the brothers Zoja. On the Swiss side, the Jungfrau still maintains her sinister priority in tempting climbers to their doom-six casualties being registered this year to her account. In nearly every case the false economy which dispenses with an experienced guide is primarily to blame, and next to that the foolhardihood which attracts the nature-student to a rare flower or mineralogical specimens on the brink of an abyss. Refuges such as those in course of erection by the Paduan Alpine Club on the Venetian ranges are well inspired, particularly when available on the sudden descent of a mist; but nothing can excuse the lack of precaution which leaves the skilled

guide out of account or which neglects the personal equation in the matter of bodily fitness for the climb. This latter condition is, as THE LANCET and its contemporaries, Swiss and Italian, have often pointed out, one of vital importance to the mountain climber, particularly when approaching the meridian of a life passed in sedentary work. Half an hour's interview with a physician previously to essaying a mountain ascent would have obviated many a casualty, due ostensibly to misplaced footing but really to cardiac lesion and cardiac failure.

ENTERICIN IN THE TREATMENT OF ENTERIC FEVER.

WE have received a copy of the Transvaal Medical Journal for March containing a paper by Mr. John Maberly of Woodstock, Cape Colony, relating his experience with a drug to which he has applied the name of "entericin" in the treatment of enteric fever. He published a paper in THE LANCET in February, 1897, on the use of a tincture of Monsonia biflora in dysentery, and the results he obtained encouraged him to try this drug in cases of hæmorrhage in enteric fever, with effects which he claims justified his expectations, so that he made it a matter of routine to administer this drug to all his cases in the third week of the disease. During the Boer war of 1900-03 he introduced the drug to the notice of Dr. W. Darley-Hartley, who employed it in cases under his charge in the Military Hospital at Woodstock. Dr. Darley-Hartley in a letter written to Mr. Maberly in July, 1903, stated that he found nothing so effective in the treatment and prophylaxis of hæmorrhage in enteric fever and that he never lost a case from this complication when tincture of Monsonia biflora had been given as a prophylactic, which he came to regard a routine in the latter part of the second and in the third week of the disease. Mr. Maberly wished to employ this treatment in the earlier stages, as he believed it would afford a curative method of treatment, but the peculiarly constipating effect of the drug in this disease proved a great objection. He therefore endeavoured to separate the active principle, and after many failures he succeeded in 1905, with the aid of an analytical chemist, in isolating a body which he describes as of stable but indefinite composition, to which he has applied the name of entericin. In the paper before us he records his results in four cases of enteric fever. The first case was in a young woman five months pregnant who was first seen on the fifth day of the disease. She was given 2 drachms of entericin every six hours, the temperature became normal on the sixteenth day of the disease, and her pregnancy went on to full term. In the second case the temperature became normal on the seventeenth day of the disease after 11 days' treatment with entericin, and in the third and fourth cases it became normal on the fifteenth day after nine and six days' treatment respectively. The cases were not kept on a rigid milk dietary, as strained meat, soups, milk, custards, jelly, and soaked biscuits were allowed. All the cases gave a positive Widal's reaction, and there were other cases of enteric fever in the district, some of which proved fatal. In the May number of the same journal Dr. R. P. Mackenzie, superintendent of the Johannesburg Hospital, records a case treated by the same drug. The patient was given doses of ½ drachm every six hours. After some days he complained of griping after its administration and it was stopped, but was resumed in doses of 1 drachm every four hours on the next day owing to the appearance of blood in the motions. No further hæmorrhage occurred. In the July number Mr. Maberly reports two further cases in which the treatment was commenced in the early stage before Widal's reaction had developed, and in both of them the dose was increased to 2 drachms every four hours. In one

case the temperature remained permanently normal after the eighth day of the illness, while in the other after the seventh day there was an irregular fever lasting several days. In both cases Widal's reaction became positive during the course of the illness. Mr. Maberly rightly deprecates the drawing of definite conclusions from so small a number of cases, but he is encouraged to hope that entericin gives promise of being a valuable drug in the treatment of enteric fever. The evidence he offers of its value is sufficient to warrant a more extended trial, and it is to be hoped that he will give details of the manner of its preparation with a view to this object being carried out.

THE ADMINISTRATIVE TREATMENT OF PULMONARY TUBERCULOSIS IN GLASGOW.

In connexion with the problem of dealing with the consumptives of a large city an interesting memorandum has been prepared by Dr. A. K. Chalmers, medical officer of health of Glasgow. In this document Dr. Chalmers draws attention to the alteration that has gradually taken place during the last 30 years in the manner of providing institutional treatment in these cases. At the beginning of that period such treatment was provided in the general and Poorlaw hospitals. But long before the present movement in favour of sanatoriums began the practice of the general hospitals in Glasgow in relation to consumption underwent a change which of itself was calculated sooner or later to raise the question of special hospitals for the treatment of the disease. Although this change would appear to have begun at a date subsequent to the discovery of the tubercle bacillus, it was determined rather by altered views of treatment than by any theory of infectivity. Between the years 1880-84 and 1907 the proportion of admissions for phthisis to the total medical admissions fell from 15 to under 3 per cent. in the Royal Infirmary, and from 16 to 2 per cent. in the Western Infirmary. Of recent years special provision has been made for the treatment of phthisis in the parish hospitals of Glasgow (272 beds) and the parish hospital of Govan (144 beds). Sanatoriums have also been erected at Bellefield (52 beds), Bridge-of-Weir (140 beds), and Lanfine (14 beds). The Poor-law institutions at Lanfine are available without charge to those who are eligible; at Bridge-of-Weir children are admitted free, males pay on an average about 15s. weekly, and females somewhat less; at Bellefield some are admitted free, while the amount paid by the others averages over all admissions 7s. 6d. per week-These institutions serve to illustrate some of the anomalies attending our present methods of providing medical relief. The consumptive pauper is able to obtain accommodation and treatment at any time in a Poor-law sanatorium, but there is no equivalent provision for the consumptive who may be just above him in the social scale. And, again, the consumptive wife is refused the provision which would be available for her husband in similar circumstances. Dr. Chalmers goes into the cost of providing sanatorium treatment for all cases in the city. He estimates that as fully 1200 deaths occur annually in Glasgow from pulmonary tuberculosis, the number of persons who become tuberculous during the year, allowing for recoveries, must considerably exceed this. By the provision of 100 beds for training purposes, that is to say for teaching patients the proper course of procedure, a number of patients equivalent to the number of deaths could be afforded one month's training at a cost for maintenance alone of about £8000 annually, plus the annual interest on the capital sum spent on site. The obvious criticism is that nothing approaching effective treatment-i.e., cure of the disease-could be undertaken in the time allotted to each patient. Dr. Chalmers then turns to

the work done by the tuberculosis dispensaries established in the city and the home visitation and supervision connected therewith, and we are in agreement with his contention that the extension of this line of work holds out the best hopes for the future. Our Glasgow correspondent reports this week the recent resolution of the health committee of his city advocating such a course, and also the adoption of compulsory notification. Finally, Dr. Chalmers's belief is that to grapple with the problem effectively it will be necessary to replace in sanatoriums the accommodation which has been withdrawn from the general hospitals in Glasgow.

THE UNIVERSITY OF LONDON AND THE MEDICAL FACULTY.

WE report in another column the proceedings at the interesting meeting of the Faculty of Medicine of the University of London on Monday last, when the fate at the hands of the Senate of the scheme for the creation of a Faculty Board was duly reported. It will be remembered that the Faculty had approved by resolution the formation of a Board which could fairly place medical views before the Senate in an authoritative way. This the three members of the Faculty upon the Senate cannot hope to do, while no coherence of view or attitude can be expected from the whole body of the Faculty. The formation of this Faculty Board was approved by the Academic Council but not, we understand, by the External Council; and now the Senate has followed the lead of the latter body, proposing to create a Board merely empowered to report to the Faculty instead of a working body desired by the Faculty which would have possessed advisory powers to the Senate, and possibly in the future some executive authority. The Royal Commission which is now sitting may be expected to take notice of the circumstances.

THE TREATMENT OF PELLAGRA.

In view of the increasing prevalence of this disease in the United States an important monograph on "The Prognosis and Treatment of Pellagra" by Dr. C. H. Lavinder has been published by the Public Health and Marine Hospital Service of the United States. As regards the treatment of pellagra, Dr. Lavinder remarks that there is no known specific for the disease, thus showing that little progress has been made since Sir Henry Holland wrote in the Medico-Chirurgical Transactions (London, 1820): "In short, it appears certain that mere medicine has done very little for the relief of pellagra." Lombroso, in his search for a remedy, got the idea of using arsenic, and the results exceeded by far his expectations. But he does not seem to have regarded arsenic as a true specific for pellagra, although considering it a valuable remedy in some cases, acting in a certain sense as an antidote for the toxins of spoiled maize, to which he attributed the disease. Of the more recently introduced preparations of arsenic it was thought well to try atoxyl and soamin, but they proved of little value in Dr. Lavinder's hands, although he was not willing to discard them as useless. He found Fowler's solution of benefit in some cases. Dr. Babcock used both atoxyl and soamin extensively at the State Insane Asylum at Columbia, South Carolina, but he did not observe any permanent benefit from the treatment They were administered by intramuscular injection in doses of 0.2 to 0.5 gramme every other day for two or three doses. followed by an interval of about ten days. He also thinks that Fowler's solution is a remedy of importance. Dr. Wood of Wilmington, North Carolina, speaks disparagingly of atoxyl as a result of his experience. It is clear, therefore, that the newer arsenical remedies are not generally so favourably regarded as the older form, Fowler's solution, which has been used by Lombroso in doses of from

5 to 30 drops, increasing the dose according to tolerance. Dr. Lavinder and Dr. Babcock tried mercury succinimide, but they achieved no results with this drug except in syphilitic cases. It proved to be quite irritating locally. At Columbia a trial was made of the method, recently advocated by Babés, of combining the use of atoxyl and arsenic trioxide, the former being injected hypodermically in doses of 0.5 gramme, and the latter being used internally in the form of pills containing 0.001 to 0.002 gramme taken three times a day, and externally in the form of an ointment containing 2 per cent. of arsenic trioxide. Turning to the serum method of treatment, Dr. Lavinder attempted to treat two patients with blood serum taken from cured cases. One patient died from pneumonia shortly afterwards, and the other showed improvement only for a short time and is not expected to recover. He remarks that he was unable to secure properly cured cases for obtaining the serum, and this may account to some extent for so poor a result. Commenting on a reported case of a cure by transfusion of blood from a cured patient, Dr. Lavinder admits the possibility that the blood from any healthy individual might have a similar beneficial result. It would be interesting to hear the result of further researches upon the condition of the blood in pellagra. Although the specific toxic properties of the damaged maize which are believed to cause it have not yet been isolated, it is not at all improbable that further research will lead to their isolation and the preparation of a corresponding antitoxin.

THE PROMOTION OF NATIONAL HYGIENE BY THE ROYAL INSTITUTE OF PUBLIC HEALTH.

WHILST pundits are engaged in paper controversy upon the possibility of saving the nation from the hygienic sins of its fathers, and politicians embroiled in party warfare impatiently push aside measures aimed at the physical wellbeing of their constituents, it is a very encouraging thing that active educational movements dealing with the art of living healthily are being carried on by more than one public-spirited society. We have alluded before to the excellent objects of the National League for Physical Education and Improvement and the more transcendental aims of the band of enthusiasts engaged in promoting "National Eugenics," and now we desire to draw attention to the action of the Royal Institute of Public Health in creating a Department of National Health, under the patronage of Her Majesty Queen Alexandra, and the vice-patronage of the Princess of Wales, and a committee of influential ladies. This department has been created by the Council of the Institute " in view of the great necessity which exists in the interests of the public health of a knowledge on the part of the people of the more simple truths connected with domestic hygiene and infant rearing," a necessity which none can deny. The work of the department at present consists of two branches, instruction and examination. Elementary and advanced courses of instruction are given by medical practitioners to those having ready access to the homes of the poor, such as district visitors, the members of the Salvation Army and other religious bodies, such subjects as food, air, clothing, sleep, cleanliness, and infectious diseases forming the staple of the lectures. Junior and senior certificates are awarded to those who satisfactorily pass the respective examinations held after these courses are concluded. At the class which was recently held under this scheme at the Clapton Congress Hall there were no less than 400 students, and certificates of proficiency were awarded to those who had passed the necessary examination at a public meeting on Oct. 18th. It is good to realise that so many foci of hygienic enlightenment have been kindled amongst

those very poor people who most need their influence. examination branch of the department's work has been established to provide an authoritative qualifying test for health visitors and school nurses, by which municipal and educational authorities may be assisted in the selection of women for those posts. From the syllabus which has been forwarded to us it would seem that this examination will be thorough; and though it will consist of written papers and viva voce interrogation we trust that these tests will be made as practical in their intention as is possible. Common-sense capable women with a sound knowledge of principles are wanted for these public health offices, not people crammed with a surfeit of technical knowledge. We have ourselves known of a nurse who admitted to having learnt several pages of a physiology book off by heart without in. the least degree understanding them; she knew the long words and was quite content. We have too high an opinion of the Royal Institute of Public Health to imagine that it will encourage this sort of false knowledge in the candidates for its hygienic hall-mark. Those who wish to hear more of these courses and examinations can do so by applying to Mr. James Cantlie, honorary secretary of the institute, at 37, Russell-square, London, W.C.

THE PHARMACOLOGY OF ERGOT.

THE great therapeutic interest connected with ergot, and the constantly changing opinions as to its active constituents, render it most desirable occasionally to review the progress that has been made. The most recent work on the subject is critically reviewed in the Journal of Pharmacology and Experimental Therapeutics for August by Mr. W. H. Cronyn and Mr. V. E. Henderson of the Pharmacological Laboratory of the University of Toronto. Summarising their own experiences and those of other workers, they conclude that most galenical preparations of ergot contain considerable amounts of the active principles, but do not show any great or marked action when given by the mouth. They consider that the doses usually recommended for these preparations are much too small. They point out that when injected intravenously a fall in blood pressure always precedes the rise, except after the administration of ergotoxin. Quantitatively, the galenical preparations of ergot show great variations in pharmacological action. They conclude that ergotoxin is a highly active alkaloid, having the properties of ergot most desired in medicine. It brings about a long enduring contraction of the walls of the arterioles, and increases the movements of the uterus. Its action is feeble when given by the mouth, but it is more marked in subcutaneous injections, and much more so when given intravenously. The last-named method is recommended in cases where a rapid and certain action is desired, either in shock or in post-partum hæmorrhage.

TYPHOID FEVER AT A SILVER MINE.

DURING August typhoid fever on a somewhat wide scale broke out in a mining camp near Cobalt, Northern Ontario, and in the town of Cobalt itself. Cobalt is situated in the district known as New Ontario, about 300 miles from Toronto, and is the centre of an active silver mining industry. During the past year or so there has been a large influx of population to the district, most of whom have been miners attracted by the promise of high wages. As in the early days of the majority of mining localities, the laws of health have been ignored, the consequence being that typhoid fever has been present to a greater or less extent for some considerable period. In August, however, matters became really serious. Cobalt having by this time a population of over 5000 was by the laws of the province outside the jurisdiction

of the Provincial Board of Health of Ontario, but as the local authorities were unable to cope with the situation the services of the board were called upon. Dr. C. A. Hodgetts, the secretary to the board, and Dr. Bell, one of the medical inspectors to the board, went to Cobalt, and under their directions efforts have been made to effect the necessary sanitary reforms. They found appalling sanitary conditions. All the wells were near the surface and the contiguous latrine arrangements were absolutely primitive. They caused more than 70 wells to be closed, warned the mine-owners that pure water must be supplied to the workers, and ordered the mines to be equipped with a dry-earth bucket system. These measures soon bore fruit, but as late as Oct. 9th, in the miners' camp outside the town, there were 56 cases of typhoid fever, and in the town itself there were 41 cases. The disease has not been of a severe type, although there have been several deaths. The mine-owners are now fully aware of their responsibilities and informed how best to proceed. They are providing hospitals for the benefit of the miners, to which all those suffering from typhoid fever are taken. In connexion with these hospitals a rather remarkable instance of religious intolerance has been reported to us by a local correspondent. He states that "the Cobalt branch of the Lord's Day Alliance objects to the delivery of milk to the hospitals on Sunday, and the chairman of the hospital board has been informed by the Express Company that they cannot deliver milk sent from Toronto to Cobalt without being liable to prosecution by the Alliance. The hospitals are thus unable to procure a sufficient milk-supply.' Religion is a very good thing, but we seem to remember that Christ expressly provided against this sort of fanaticism when he pointed out that the Sabbath was made for man and not man for the Sabbath.

APPENDICITIS WITH HÆMATURIA.

In the New Zealand Medical Journal for August Mr. P. H. V. Hammersley has reported a case of appendicitis in which a very rare complication occurred. In 1905 he saw a lady "of mature age" who complained of attacks of dyspepsia accompanied with pyrosis, nausea, pain, and flatulence. The uterus was retroverted and retroflected and the right kidney was freely moveable, but there were no signs of disease of the vermiform appendix. In August, 1908, she was again seen, and said that every three months she was seized with vomiting, rigors, and colic. These symptoms subsided, and at the end of the second day she noticed that the urine was tinged with blood. The attacks were not influenced by menstruation but, though more or less periodical, were provoked by unwonted exertion. In November Mr. Hammersley saw her during an attack when the symptoms had subsided. The urine was so deeply tinged that it looked like pure blood. The right kidney was freely moveable but not tender, and there was no pain over the appendix and no abdominal rigidity. The temperature and pulse were normal. The urine did not contain anything abnormal except blood, and cystoscopy showed only a little pouting of the right ureteric orifice which in an ordinary case would not have been regarded as worthy of note. Skiagraphy yielded no evidence of calculus. At the end of January, 1909, Mr. Hammersley had an opportunity of seeing her at the beginning of an attack. After a few hours' malaise, nausea and vomiting of bilious fluid commenced, then a rigor supervened, the temperature rose to 102° F, and the pulse to 112, and colic set in. After 36 hours profuse perspiration and sleep followed. All the symptoms pointed to Dietl's crisis, but the kidney, which was easily palpated, was not in the least tender. On the other hand, there was a distinct feeling of fulness over the appendix, and pain was produced on deep pressure. No blood

was passed in the urine during or after this attack. Chronic appendicitis was diagnosed. At the end of February a cystic chronically inflamed appendix, evidently on the point of rupture, was removed. The appendix was bound down by adhesions to the back of the excum and ascending colon and practically lay upon the right kidney, which appeared to be normal and showed no sign of stone. The attacks ceased and the patient's appearance much improved. Mr. Hammersley suggests that by extension of the inflammation from the appendix to the adjacent kidney all the symptoms of Dietl's crisis and even the hamaturia were produced.

THE FIFTEENTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

On the invitation of the Department of State of the United States Government the Fifteenth International Congress of Hygiene and Demography will meet for the first time on the American continent in Washington, D.C., from Sept. 26th to Oct. 1st, 1910. Section 3 of this Congress will be concerned with the Hygiene of Infancy and Childhood and of the School, and will discuss matters of the utmost import to all who are interested in public health and education. The President of this section will be Dr. A. Jacobi and the Secretary Dr. Luther H. Gulick, and these gentlemen will be glad to hear of any original work that is being done upon any branch of these subjects. Our own country at the present time offers a singularly favourable field for observations in school hygiene now that the medical inspection of school children and its corollary—the treatment of those found defective—have become thoroughly established amongst us. and we are sure that some important contributions to the proceedings of the section will be made by British medical men engaged in school work and in the investigation of children's diseases. The sectional bureau is at 1, Madisonavenue, New York City, where the Secretary may be addressed.

PUNCTURE OF THE LUNG AS A DIAGNOSTIC PROCEDURE.

WE publish in another column of this week's issue an interesting paper by Dr. Thomas J. Horder in which the value of puncture of the lung is carefully discussed from the point of view of the light it may throw upon the diagnosis of obscure conditions within the lung. Puncture of the pleura to demonstrate the presence of fluid and to establish its character is, as Dr. Horder points out, a process which has been in general use from a period long anterior to the methods of modern clinical pathology, though these have considerably extended its value. Dr. Horder shows how the investigation of the few drops of blood-stained fluid obtained in a so-called "dry" tapping—that is, in a case where no fluid is found in the pleura, but the lung is pierced insteadmay throw light upon the diagnosis, and further suggests that the deliberate puncture of the lung in certain cases may yield information of great importance in regard to diagnosis and treatment. The types of case suitable for puncture of the lung are, he suggests, those with signs of consolidation of the lung where careful examination of the sputum fails to reveal its nature, and cases of abscess of the lung and bronchiectasis. In regard to the manner of performing the puncture, he recommends the use of a good-sized needle attached to a syringe which has been recently boiled and contains no chemicals to interfere with the subsequent culture of the organisms obtained. After the needle is inserted into the lung the piston is withdrawn about an inch and then the needle is extracted, whilst the skin is supported by the fingers and thumb of the left hand. Various examinations, either bacteriological or cytological, may be made of the fluid obtained. Dr. Horder gives some illustrative cases in support of his advocacy of the procedure, and further claims as an advantage the fact that it may be the only means of obtaining a culture to prepare a vaccine for the treatment of localised infective conditions within the lung. The procedure is one which is certainly deserving of more extended trial, since it is obviously a valuable method for diagnostic purposes. The only conditions which suggest themselves as disadvantages are the possibility of infection of the healthy pleura or of the needle track in septic cases, and the occurrence of hemorrhage from wounding a vessel or an aneurysm in a pulmonary cavity.

MEDICAL OPINION AND PUBLIC APATHY.

THE two great medical services of the country, the sanitary service and the Poor-law medical service, both working under the Local Government Board, are the expression of the influence of the State upon the public health of the people. A new journal, the Medical Officer, has lately made its appearance, and a very promising appearance, which has for its object the dealing with the various problems of administration as they arise, with particular reference to the medical executive. The issue of this journal, which is dated Saturday, Oct. 9th, contains much interesting matter for medical men in Government and municipal services, and the leading article for that week is devoted to the insanitary condition of Gravesend, to which attention has within the last few weeks been prominently directed by Dr. R. J. Reece's report to the Local Government Board. Our contemporary expresses surprise that it is possible for a local authority, such as that of Gravesend, to continually flout the central health authority and to maintain insanitary conditions which were drawn attention to on behalf of the Board by Mr. Netten Radcliffe in 1877, by Sir Shirley Murphy in 1885, by Dr. Theodore Thomson in 1893, and now by Dr. Reece in 1909. But this story of Gravesend is in no sense alone, and a careful perusal of the reports of the medical inspectors of the Local Government Board will bring to light numerous instances in which repeated visits of inspectors have been made in years gone by, but where the conditions are now but little altered from those which obtained at the date of the first inspection, perhaps a quarter of a century ago. The problem of how to deal with these recalcitrant authorities is a very difficult one, and it cannot, unfortunately, be said that the creation of county councils has served to stimulate local opinion and activity in the manner which was once expected.

PREVENTIVE MEASURES AGAINST MOSQUITOES.

MALARIA is endemic in most tropical and subtropical regions where precautions are not taken against mosquitoes, and the story of a recent application of medical entomology to practical cases is an instructive chapter in the history of sanitation. It is now a matter of common knowledge that measures directed mainly against the breeding-places of the insects have proved successful in various parts of the world. An experiment on a comparatively small scale, but no less effective, has recently been made by Major P. G. Elgood, director of the Police School in Cairo, and was described by him in the Cairo Scientific Journal for July last. In the autumn of 1906 this school occupied an old palace containing from 150 to 200 comparatively small rooms, together with an average of one cess-pit to each two rooms. Mosquitoes abounded and were so troublesome that Major Elgood, who had already had experience of them in Burma and elsewhere, could not sit in his quarters after sunset, and the cadets were unable to obtain sleep. The public health department then came to the rescue, and he states that

when its preventive measures had been in operation for a few weeks the palace seemed to be more free from mosquitoes than any flat or club which he was in the habit of visiting at the time. In the summer of 1908 the school moved into new quarters at Abbassia, where it was soon found that the desert isolation of the locality was no protection against mosquitoes. Major Elgood, however, guided by the public health department, dealt with them by a simple method. Once a week a third of a teacupful of crude petroleum oil was poured down each of the 182 latrines, sinks, and other possible mosquito-breeding places which exist in the school. Twice a week each receptacle of water was emptied and filled. The result was that on the occasion of a visit made by an inspector of the public health department no mosquitoes could be found in the school, although all latrines and other likely places were searched by him. No special men were in charge of the work and the cost was estimated at about 10s. a month. Major Elgood draws particular attention to the simplicity and cheapness of the preventive measures which satisfied him so well. He also mentions, incidentally and without comment, that the prevalence of dengue in the school declined very much after the removal from Cairo to Abbassia.

THE MEDICAL TREATMENT OF LONDON SCHOOL CHILDREN.

THE education committee of the London County Council on Nov. 3rd approved and forwarded to the Council for sanction further arrangements with the hospitals for the medical treatment of children attending the public elementary schools of the metropolis.1 The day schools subcommittee reported that it had communicated with 55 hospitals and had received replies from 50. Of these 18 had either not expressed any desire to cooperate, or were sympathetic but unable to undertake additional work, and 5 are treating some 390 children a week without charge. The authorities of the remaining hospitals desired financial assistance, and the committee had negotiated with them on the basis already approved by the Council—viz., a payment not exceeding £50 a year for each additional medical assistant (working one half-day a week) and 2s. for each child treated. Final terms had been suggested in respect of 14 out of these hospitals, and the committee recommended that, as a beginning, agreements be entered into with eight of them to provide treatment for eyes, ears, and skin ailments-viz., Belgrave Hospital for Children, Clapham-road, S.W. (1760) children); Charing Cross Hospital, S.W. (2200); Hospital for Diseases of the Throat, Golden-square, S.W. (1000); King's College Hospital, Lincoln's Inn-fields, W.C. (500); London Hospital, Whitechapel-road, E. (4750); Metropolitan Ear, Nose, and Throat Hospital, Grafton-street, Tottenham-courtroad, W. (500); Royal London Ophthalmic (Moorfields) Hospital, City-road, E.C. (for not less than 3000 or more than 6000); St. George's Hospital, Hyde Park, W. (2000); and that the acceptance of the offer of the committee of the Charing Cross Hospital to provide treatment by means of X rays for 25 children attending public elementary schools be confirmed, expenditure not exceeding £35 being sanctioned in connexion therewith. The subcommittee explained that the London Hospital, which in July agreed to give free treatment, had withdrawn from that arrangement and wished to enter the class of hospitals to which the Council was prepared to make grants. It also recommended the Education Committee to accept an offer by the Hampstead Council of Social Welfare to provide gratuitously for one term treatment for the Hampstead children. The subcommittee estimated that provision has

¹ See THE LANCET, July 31st, 1909, p. 312.

still to be made for upwards of 21,000 children. In the discussion on the report an amendment to insert in the agreements with the hospitals a stipulation that the waiting-room and other accommodation should be satisfactory to the Council and the hours of treatment convenient to working-class parents was rejected, Miss Lawrance and other supporters of the committee's proposals urging that the amendment would give offence to the hospital authorities, and that if such important work could be entrusted to them at all they could be left to carry it out under the best conditions. The recommendations of the subcommittee were accordingly approved.

THE AERO CLUB OF THE UNITED KINGDOM.

THE Royal Automobile Club Journal of Oct. 21st publishes a special supplement drawn up by Mr. F. H. Butler, the founder of the Aero Olub of the United Kingdom, which gives a chronological summary of work done by members of that club and others during the period 1901-09. The Aero Club was founded at the end of September, 1901, and was registered on Oct. 29th of the same year as a limited company in connexion with the Automobile Club. The events mentioned in the summary are chiefly concerned with balloons, for we in these islands are, or at any rate were until very recently, far behind our continental neighbours in the art of flying by aeroplanes. Still, on Dec. 4th, 1908, Mr. Moore-Brabazon flew 450 yards in an aeroplane at Issy-les-Moulineaux, Paris, and on Sept. 8th, 1909, Mr. S. F. Cody flew for 40 miles in his biplane at Aldershot. The science of aeroplaning has apparently but little to do with medical matters, but in a former issue we drew attention to the difficulties which the new mode of transit might bring about in the future with regard to the spread of infectious diseases such as cholera or plague. The "avia loca" of the air know no frontiers, and flying machines will certainly have to be taken into consideration in any further regulations, such as the existing Venice convention, which may be agreed upon among the nations to prevent the spread or dissemination of disease. Another way in which flying machines may interest medical men in the not very far off future is their use as hospital "ships" or means of transporting the sick to regions of the earth where certain climatic conditions obtain. This use of aeroplaning has been already set out in realistic fashion by Rudyard Kipling, in his wonderful fantasy, "With the Night Mail." No one who has read it will forget his description of the Benedicite sung at dawn on the hospital boat for "consumptives bound for Frederikshaven or one of the glacier sanatoriums for a month." The date is 2000 A.D., but when we look back at the progress in scientific invention between 1859 and 1909 it may be that another 50 years will see Mr. Kipling's dream no longer a dream but a reality.

His Majesty the King visited the National Hospital for the Paralysed and Epileptic, Queen-square, on Nov. 4th, and opened the jubilee extension wing of the hospital.

THE Local Government Board, acting on the request of the London County Council, has ordered that the Notification of Births Act, 1907, shall come into operation in the metropolis on Nov. 30th next.

WE have been notified that the following members of the medical profession have been elected as councillors on the London borough councils, but possibly the list is incomplete: Camberwell, Mr. F. Lonnon and Dr. D. M. Serjeant; Finsbury, Mr. W. Lauzun-Brown; Fulham, Mr. J. J. Edwards; Hampstead, Mr. C. W. Cunnington; Islington. Dr. G. Madden and Dr. Kate Haslam; Kensington, Dr.

F. H. Anderson and Dr. F. H. Alderson; Paddington, Dr. J. Thoresby Jones; St. Pancras, Dr. R. M. Beaton and Dr. Paramore; Stepney, Mr. M. Feldman; and Westminster, Dr. Henry Dutch.

A TELEGRAM from the Governor of Mauritius to the Secretary of State for the Colonies states that 21 cases of plague with 13 deaths were reported during the week ending with October.

THE next meeting of the British Medical Association, as has been already announced, will take place in London, and Mr. Butlin, President of the Royal College of Surgeons of England, has been nominated President-elect. It is anticipated that the annual meetings of the Association in 1911 and 1912 will be held in Birmingham and Liverpool respectively.

THE friends and pupils of the late Professor Arthur Gamgee have initiated a fund which is intended to mark their high appreciation of his eminent services to science and his life-long devotion to the prosecution of knowledge. Subscriptions to the Gamgee Fund may be sent to Professor Arthur Schuster, Victoria Park, Manchester; Dr. A. D. Waller, Physiological Laboratory, University of London, S.W.; or Dr. G. A. Buckmaster, University College, London, W.O. A meeting of supporters of the movement will be held shortly, the date and place of which will be announced in due course.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A COMITIA was held on Thursday, Oct. 28th, Sir R. DOUGLAS POWELL, Bart., K.O.V.O., the President, being in the chair.

The following gentlemen having passed the required examination were admitted Members of the College:—William David Keyworth, M.B., B.C. Cantab., and Charles Joseph Singer, M.B. Oxon., L.R.C.P. Licences to practise physic were granted to 104 gentlemen who had passed the necessary examinations.

The PRESIDENT announced that the Jenks Memorial Scholarship had been awarded to Mr. Phillip Dennis Scott. He also announced that the adjudicators of the Weber-Parkes prize and medals had decided upon the following subject for the next competition: "The influence of mixed and secondary infections upon pulmonary tuberculosis in man and the measures, preventive and curative, for dealing with them."

The following communications were received: 1. From Professor Emil Fischer thanking the College for the award of the Baly medal to him. 2. From the secretary of the Royal College of Surgeons of England regarding proceedings of their council on July 29th and Oct. 14th last.

A report was received from Dr. F. W. Pavy, the College representative at the International Medical Congress at Budapest. On the motion of the PRESIDENT the thanks of the College were returned to Dr. Pavy for the service he had rendered to the College.

The audited accounts for the year ending Sept. 29th last were laid before the College. The quarterly report of the College Finance Committee, dated Oct. 21st, was received and adopted.

The resignation of Dr. P. H. Pye-Smith as a member of the Executive Committee of the Imperial Cancer Research Fund was received, and Dr. A. Newsholme was appointed a representative of the College in his place.

Dr. Norman Moore was re-elected a member of the Committee of Management.

The books and other publications presented to the library during the past quarter were received and the thanks of the College ordered to be returned to the donors.

After some further formal business the PRESIDENT dissolved the Comitia.

THE INFLUENCE OF MIND AS A THERAPEUTIC AGENT:

ADDRESS BY DR. CLAYE SHAW.

A WELL-ATTENDED meeting was held at the rooms of the Harveian Society of London on the evening of Oct. 28th, the President, Dr. CHARLES BUTTAR, being in the chair. After the formal business the President introduced the subject of the evening's discussion—namely, "The Influence of Mind as a Therapeutic Agent," saying that his society had brought it forward, believing that the medical profession must take cognizance of the growing interest of public opinion in psychic methods of treatment. He had much pleasure in calling on Dr. T. Claye Shaw, emeritus lecturer on psychological medicine at St. Bartholomew's Hospital, to open the

The Validity of Suggestion.

Dr. CLAYE SHAW said: Mr. President and Gentlemen, I have accepted the honour of introducing a discussion by this society on the influence of mind as a therapeutic agent because it gives an opportunity to those who employ this line of treatment to give their results and their methods to the criticism of a practical audience desirous of knowing the grounds upon which we are asked to receive a process which differs in principle from the ordinary physical treatment adopted by the physician and surgeon. When any particular theory is brought forward and recommended as fit for application by responsible medical men who have specially studied the subject and have committed themselves to writing upon it, it behoves us to examine its claims impartially, and if the basis appears to be sound and the results credible it becomes our duty to avail ourselves of it in the interests of patients. It matters not that irresponsible and unqualified persons have adopted the arguments and the processes laid down by certain practitioners; the same might be urged against the use of ordinary medical and surgical therapeutical aids because some of these are employed by bone-setters and the exploiters of quack remedies. We do not decline to use electricity and magnetism because they were brought to notice by laymen, nor to treat hydrophobia by inoculation because it was introduced by a chemist. The function of a society like this is to analyse the pro and con arguments of a matter placed before it, so that authority may be given to the members to employ or to reject the conclusions from the evidence brought before them. As seen nowadays the influence of mind as a therapeutic agent is chiefly practised under the term "suggestion," derived from suggerere, to bring under notice or to present; and it is familiar under the term "hypnotic suggestion," though all suggestion is not of the hypnotic form. Our discussion-prefix might therefore be "on the validity of suggestion" are there any grounds for its acceptance into our pharmacopœia of remedies? can mental influences be brought to bear on structural defects? are there mental states which can influence bodily conditions and which can be brought into play to affect them?

Let us have a clear conception of what we mean by "suggestion." It is the insinuation of a belief or impulse into the mind of a subject by any means, as by words or gestures, usually by emphatic declaration; also the impulse of trust and submission, which leads to the effectiveness of Psychology"), "Suggestion is a process of communication resulting in the acceptance with conviction of the communicated proposition in the absence of logically adequate grounds for its acceptance." Perhaps there are people who take objection to the latter part of this dictum, because in some cases it would seem that there might exist logically adequate grounds for its acceptance, though the person acted upon might not be able to appreciate them. Suggestion is no new thing-it is of old application and was used in the different times of Tertullian, St. Augustine, Scaliger, Hobbes, and Locke. The basis of much of the treatment by suggestion is the unseen and the intangible, and it rests on what is called the spiritual mind. It postulates the exist-ence of conative processes, such as Will, Faith, Power of Attention, treating these as actual extities which can be influenced by being strengthened when weak or called into energy when dormant. In the majority of those who seriously entertained. In this, as in other matters where

practise it there is no idea of physical alteration in the sense of producing a change in tissue, their object being to strengthen will power and certain lines of thought, whilst weakening others which are adjuvant to the existing conditions of ailment. Others, however, do not go as far as this -they still appeal to what they call the entities, whilst acknowledging that the revival or the strengthening of these entities has an appreciable effect on the nerve structurethe reverse process, the influence of structure or material on the mental processes, they must ignore, because the dependence of mind upon structure is to them not necessary. They may perhaps go so far as to allow that the exhibition of proper diet, of tonics, &c., is useful as enabling the "mind" to act upon an improved tissue, which was before this physically impaired, and therefore incapable of playing its subsidiary rôle as the exponent of what the "mind" wants or intends, but this is not the primary object of the treatment, which is the strengthening or the correction of an intangible essential principle which overrides all other conditions of whatever sort they may be. This must be so, since the supporters of treatment by suggestion state that they have cured epilepsy, locomotor ataxia, neurasthenia, &c., conditions which most people associate with organic disease of tissue.

At the British Medical Association held at Exeter in 1908 when the discussion on treatment by hypnotic suggestion was in progress one distinguished member unhesitatingly affirmed that by his methods he had succeeded in effecting cures in cases of the kind I have referred to, and though histories and exhibition of the cases could not, in the circumstances, be given, the *ipse dixit* of the reader of the paper was received as being the truthful experience of a qualified and conscientious medical man who had clinically investigated the pathological conditions which he reported to be cures. There are, then, two schools: the one says that there is a purely mental element which is susceptible to influence by direction, by dictum, by appeal to as a primary and separate agent, and there is another which regards mental conditions as inseparably associated with nerve states, which denies the existence of such separate entities as will and active attention except in so far as they are exhibitions, the result of nerve states, secondary to, or parallel with, definite activities of the nerve elements.

The difference between the two schools is important; the one which we may call that of the unfettered or free thinkers does not really require any training at all in medical matters and very often it has none. upholders deal with an impalpable (and so far indemonstrable) something which they cannot materialise, they have no surgical cabinets, no anæsthetics, no pharmacologia, they appeal to the individual to cure himself, or to receive from them an authority which they will incorporate and transform into his will, and they try to assist him by taking upon themselves the responsibility of "suggesting that such and such results will follow the cultivation or employment of a definite mental process which they may, or even may not, indicate. In its extreme forms no education is required for this. The man who has studied the nature of disease and is unable to separate structure and function is pitted against him who violently dislocates the two and elevates the latter (function) into an independent and controlling position—these function-specialists forming the class called faith-healers, exponents of which doctrine are to be found in every section of society. Still there are many educated medical men of position and reputation who resort to suggestion as a remedial agency either alone or in combination with other medical and surgical methods, and though it may be difficult to say how much of their success is due to the one or the other factor of the combination, or even to the combination itself, yet people who have the interests of their patients at heart want to know, if possible, how much truth there is in the theory of those who employ suggestive treatment. They ask for information as to whether there is such a thing as mental influence upon structure (whether sound or morbid). They want to know how much of what had better once and for all be called "humbug"-if anyenters into the composition of treatment by suggestionwhether the air of mystery with which it is often associated is really part of the paraphernalia of the charlatan, whether the vaunted success is in fact merely that of the quack, or whether there is so much truth in the process that it must be

speculation exists, when the possible comes in the probable (the capability of proof or of proving) must be eliminated from consideration. We can scarcely avoid discussing the present position with regard to the spiritual life, because it is with this that suggestion is concerned. Is there such a thing? Is there, apart from the bodily tissue, a something which is independent of it which can operate upon and be affected by this body, which can be recognised as plus or minus in its power of action and which can be used by the patient for his own advantage? When we suggest to a person that he shall exercise his will are we not asking him to influence one of his ultimate faculties? How is his will to be influenced? What is the controlling agency that is to whip up or to put the brake on the dormant or the perverted will? Is there a higher will somewhere in the background? Yes, say the religious party, there is, and this is what we call the Deity, and He must be petitioned to give power to use the will in the right direction. Does the hypnotist, then, or the suggester, make himself into a deus ex machina? Does he impose his own will on that of the patient, and arouse it or guide it in a vicarious manner? If there is no such spiritual world, no such Deity, no such Essence, no such, as Häckel calls it, "gaseous vertebrate, outside the body as we know it, then millions of men have been for ages and now are mistaken, and immeasurable oceans of blood have been spilt over a myth. The teaching of the Church in all its forms is by suggestion and, what is linked with it, by authority. We are told—not asked, but told—to believe in what we have never seen, and cannot objectively prove.

The greater our experience the more we must acknowledge that there are possible powers and influences which, however we may eventually succeed in grasping them, are at present unknown to us more closely, and it is this indefiniteness, ignorance, and want of precision on our part which are made the ground of the spiritualists, the hypnotists, and the suggesters—our terra incegnita is their playground. Nor can we say that they are wrong. When modern science has demonstrated the actual truth of bombardment by ions as the cause of magnetic storms and the phenomena of the aurora borealis, when the composition of matter is said to consist of concentric whorls of electric ions rotating with inconceivable rapidity, who is to say to what at present unseen and unknown agencies we may not yet be introduced, or that our feelings that a spiritual world does exist may not be brought within actual demonstration? The modern school of psychology is absolutely materialistic in its teaching. It insists that Will, Attention, and conative processes are results, not causes, and if so that there are, of course, no such things as primitive faculties in the direction of compelling forces. But however strongly teachers and lecturers may be necessitated to inculcate this view it does not follow that they are quite satisfied with it, and instances are not wanting where men who have ceased teaching but not thinking find themselves saying, "Now that my teaching is done, I am constrained to own that there is yet something to be explained—'I will' goes beyond 'I must.'" Take the three processes of Voluntary Action, Attention, and Emotion. Modern psychologists say that the two former can be analytically split up into certain components, but that they depend chiefly upon the strength of the last (Emotion), but we know nothing of the real nature of Emotion. In recent lectures Dr. Mott has given the results of a most learned investigation of Emotion, entering fully into all that is known of its connexion with bodily and visceral states; but with deference I submit that we are still no nearer the understanding of the real nature of Emotion than we were, and if so then we cannot understand any more the real nature of the conative processes. Why is one person more emotional than another? What visceral or nervous condition tends to make Emotion strong or weak? I may have the fear of handling snakes, but when I see others doing it with impunity and am shown why they can do so my fear goes, so that Fear was a certain mental state which was changed by suggestion and further experience into confidence. The suggester would say, "By telling the person that there was nothing to fear, by continued insistence, combined with ocular demonstration, I have brought about a change in Emotion and with it a change in Will and in power of Attention. I have not imposed my will on him, but I have created a Will in himself by altering the factors which go to form it and thus creating a mental states from the point of view of the patient; in this

new function." Note, however, that the change was a gradual one, perhaps due to change in tissue—i.e., to new association-tracts being trained and aroused by physical processes, or, as they would say, by psychical ones. If they are correct—these psychical purists—there is a school in which ordinary medicine and surgery have little part. The study of Psychology is almost unknown in the medical curriculum. Of what use, we say, is it to study the intangible which has no basis capable of physical treatment when we know that we have a material at hand which when impaired or affected renders manifest mental obliquities? Stay, are we quite sure that mental defects and aberrations are necessarily connected with structural defects? Are we sure that people who think differently from the majority, and who cannot be brought to think in harmony with them, are therefore insane and impaired in structure? Is insanity always the result of diseased structure, or may it not be associated with a tissue which is somewhat different in kind and function from what is usually met with? There are some forms which lead us to think so. Most people concern themselves only with the structural side; they say "we know nothing about the other, therefore we do not trouble about it"; the others say, "We find from our experience that there is a mental world which can influence the physical, therefore we cultivate it." If these are wrong, if psychical processes cannot affect brain structure, what is the use of telling a man that he can do this or that if he tries—putting the active energy first. Without doubt many of us actually do use suggestion without noticing it. We raise hope or we inspire confidencehow? By personality, by arousing dormant tracts of thought. In the presence of one mental state it is difficult to recognise that there are others really existing (but dormant) of the opposite trend. That a person feels in a depressed way does not imply that the brain condition which is correlate with joy and contentment does not exist, it only means that the dormant state is overshadowed by another; this is very important, for in it lies most probably the explanation of treatment by suggestion, raising it into a reasonable hypothesis.

It is then not necessary to assume the supernatural and to profess to treat an essence without influencing the physical substratum, for the above shows that structure may be influenced by psychical processes, but it is in a physical manner. Take an instance of malignant disease-e.g., cancer of the rectum; by the operation of inguinal colotomy we can check the growth by removing irritation and by giving Rest; so with nerve affections, by diverting the current of thought and so giving Rest, during which time the morbid processes may become quiescent and may disappear. Most of us use Suggestion without perhaps appreciating what we are doing e.g., the annual holiday, during which we forget the work which has reduced us to a state of mono-ideism is nothing but suggestion—the comedy when we are in the doldrums is only suggestion. I have it on authentic evidence that during the great earthquake at Valparaiso paralytics jumped from their beds, as also did people with actual pneumonia, and moreover that they were cured. Of course, in all these processes there are secondary factors which contribute to the improvement or cure-e.g., the physiological changes brought about by Rest or Move ment-in whichever direction suggestion was nrged-but the Suggestion, or change of ideas, was the primary thing. When there is intense mental concentration all the paths of association which are en rapport with the dominant idea are enlisted to such an exclusion of others that for the time being these may be quite dormant, and so the ecstatic or the martyr at the stake feels nothing; it might even be possible to "hold a fire in the hand by thinking of the frosty Caucasus!" Much of the modern treatment of lunacy is suggestive—e.g., the dances, concerts, games, and gymnastics have the object of rousing dormant tracts, and the assurance that there is "nothing the matter" has had the best effects upon people who thought they were ill; but then it requires the man who gives the opinion to be sure of his facts. The quack, who may be a clever observer though ignorant of underlying morbid conditions, is often successful because he is a psychologist; he has a personality, he has perhaps studied trends of ideas, he is able to put himself en rapport with the trend of the patient's mind. I find that in dealing with mental impairment it is necessary to cultivate

way we may often anticipate and demonstrate what he was trying to conocal, and so you get his confidence and he will do what you tell him. To accomplish this some employ Mystery, anything to compel attention. And however we may be inclined to condemn such practices as "theatrical" and call them "tricks," these aids may be necessary to attain the ends. Thus I can understand that with the view of employing Suggestion a professional, right-thinking, up-todate man might deem such things as dress of a certain colour and shape necessary, or an approach of a certain formal nature, or a laying-on of hands in a definite way, a studied silence and a fixed gaze, part of a legitimate treatment, but they must be done with a true and complete knowledge of the actual condition of the subject.

Clever amateurs may be successful where the ordinary professional man fails, not because of supernatural powers, but because they are by nature more acute students of the trend of mental states, though they are dangerous and may do harm by not ceasing in time, or by engrafting a morbid trend, or by unscrupulous uses of their knowledge for their own private ends. After all, specialists in suggestion are not very numerous. Why are there not more of them if it is so valuable a remedial agent? It is certainly a lucrative line of practice and its adoption has no terrors for the patient. I take no account of Theosophists who believe themselves to possess a knowledge of the Divinity and His works by supernatural inspiration, nor of "Christian Science" devotees whose methods seem to me ridiculous, but, confining myself to those medical men who use suggestion pure or combined with hypnotism, I would ask, Must there not be valid ground for using it as a therapeutic agent? and I would add that personally I believe there is. One thing is certain—we are not all able to use it beyond a very limited extent. If, as its advocates urge, they are able to effect cures in cases where all other forms of treatment have failed, their claims must be received with the greatest consideration. Those who practise it will tell you that they cannot explain how they do it -that they have found out, almost by chance, that they have a power, a personality, which they themselves cannot understand, of influencing people affected more especially with functional ailment and perhaps indirectly even organic disease. Does this peculiar innate power account for the small number of specialists in this occult process? It is with such conditions as chronic inebriety, opium, or drug habit that suggestion is most powerful; with acute insanity I have not seen it successful, and though it has been fairly tried in asylum practice it has not obtained general recognition as a therapeutic agent. In the chronic alcoholic or drug-taker excess may be practised for a considerable time without irreparable damage to tissue, but in all these cases there is intense Desire, of which the chief constituent is *Feeling*. Now feeling we know may rise to a great height, but only to a *limited* height, and when unsatisfied it tends to disappear. We know by experience (as in the confessions of De Quincey) and there are few of us who cannot quote from our own experiences of alcoholics, smokers, and druggers, that by the exercise of will these habits may be overcome and the desire disappear, and this is accomplished by the arousing continuously of new interests and lines of thought. But when disease is established, when more than mere habit has supervened, there is a force acting against us which by its constant pressure prevents the opening up of other tracts and does not permit the feeling to die down.

It is not always easy to distinguish between functional and organic disease, and bearing this in mind we may be inclined to side with the exponents of suggestion that no case should be relegated to the scrap-heap of failures without this method having been tried. The Harveian Society will, bearing in mind the logical and experimental method of its great namesake, acclaim any addition to the list of therapentic agents for employment in the treatment of disease on satisfactory evidence that it has legitimate grounds for what it claims, and there are present to-night some of those who are competent to place these grounds for their claim to suggestion as a therapeutic agent before you.

The Pros and Cons of Suggestion.

Dr. J. MILNE BRAMWELL, in beginning the debate, first remarked upon the confusion existing in the minds of medical men between the effects of the drugs which they administered and the suggestive effect which these drugs had upon the patients' minds. Ellioteon, as well as Braid, the father of hypnoxism, had insisted that it was of the

utmost importance to determine the amount of mental influence exerted by drugs. Such distinguished physicians as Sir Andrew Clark and Sir William Gull had attained real and great success with the use of the simplest remedies in very different conditions, and the secret of the success of such men was that probably their patients caught the inspiration of their own enthusiasm. Dr. Bramwell also quoted Dr. Hack Tuke and Professor Benedict of Vienna; the former held that suggestion could produce a therapeutic effect unattainable by drugs alone, while the latter attributed curative results to magnets, which were really due to suggestion alone. This being so, was it not better, Dr. Bramwell asked, to use suggestion consciously than unconsciously? James Braid's earlier experiments in hypnotism were well known, but it was not so well known that after he had gained more experience he discovered that therapeutic effects could be obtained as well by simple suggestion as by inducing the hypnotic sleep, and that he had recorded that not 1 in 10 of those he cured passed into any condition resembling sleep. Bernheim and others had come to the same conclusion, in which the speaker also agreed. Dr. Bramwell then proceeded to quote some striking cases in which the utmost benefit had resulted from treatment by suggestion in people who had been invalids for many years, or who were suffering from acute neuroses which had reacted to no other treatment. Systematised suggestion, he said, would cure people even when they came absolutely disheartened and insisting that no power on earth could cure them. He instanced two cases of la grand hystéric, one with suicidal tendency, and a case of neurasthenia that had lasted for over 30 years, all of which had been cured by suggestion. Perhaps the best results were obtained in cases of obsession, and he would ask what drug could influence an unfortunate patient who dreaded to be in an open or a closed space, or had, for instance, a morbid fear of cats. One of the most remarkable of his cases was that of a schoolmaster with an obsession that he must throw himself out of his class-room window. He was cured in six weeks by suggestion, and has been well and doing useful work ever since. Dr. Bramwell could not explain the power of suggestion, and he did not lay claim to any mysterious influence over his patients. He was glad that the value of this branch of treatment was at last being recognised by the medical profession, and the Society of some 80 medical men interested in the subject which had been recently formed testified to the growing belief in suggestive therapeutics.

Dr. T. SEYMOUR TUKE, speaking as an alienist, was unable to make any encouraging report of the use of hypnotism and suggestion amongst insane patients. He considered that such agents could only operate in insane cases which were mentally and physically sound except on one point, cases, that is, which had not lost the power of attention and concentration. He had found suggestive treatment marvellously effective in cases of inebriety in which the will was under some sort of control, and admitted that possibly the mental physician, who was constantly in contact with his patients and was able to get into a sort of communion with the minds of some of them in a manner not attainable in casual conversation, with care and patience might exercise a slow and real suggestive influence over them, so that a cure might ultimately be effected, however gradually. It was, indeed, hard to attribute such a cure definitely to suggestion, but if suggestion could shorten any case of insanity it should be welcomed by those engaged in the treatment of that disease.

Dr. C. LLOYD TUCKEY said that he had been using hypnotism as a therapeutic agent for 20 years, during which time an enormous change had come over the medical profession's attitude towards its employment. Many diseases, such as genuine dipsomania, could not be reached by drugs. He had cured many such cases by hypnotism, as well as other intractable conditions, such as three cases of Ménière's disease. He had never known hypnotism do any harm to a patient, and he considered the medical profession ought to have this remedy at hand for use in suitable cases. It was unfair to medical students not to teach them anything about hypnotism and suggestion. There were no public facilities in this country for a man to learn the application of these valuable methods, either before or after graduation. When the medical per fession as a whole had been trained in the knowledge of

psychotherapeutics many cases would be prevented from going to quacks for such treatment.

Christian Science.

Mr. STEPHEN PAGET said that he had been invited to take part in the discussion only because he had lately been inquiring into the works of Christian Science, and into those of the Society of Emmanuel in London. He had never studied either psychology or the care of the insane or the methods of hypnotic treatment. In all that he had been saying about Christian Science and the present revival of "spiritual healing" he had addressed himself "to the man in the street," and he asked leave to speak as that man's representative. The man in the street wanted just now a definite and precise list of those cases which were open to mental healing, and a similar list of those which were not. He wanted to know the exact difference between functional diseases and organic diseases. He wanted to know under what conditions, and to what extent, and by what physical processes, hope and faith and love took part in a man's recovery after operation, or a man's power to pull through a long illness. If it were possible for a committee of the medical profession to draw up and publish a clear statement in general terms as to the diseases which were open to the influence of mind, and the diseases which were shut against that influence, such a statement would be of great public service. Only, to be acceptable to the man in the street, this statement would have to adventure beyond the bounds of psychology. And if the present discussion were to be of any public service they must adventure beyond those bounds; they must not be limited inside one set of ideas, but must look out over all facts of experience. The subject of the discussion extended beyond the authority of experts in psychology, such as were leading the debate. They ought to have non-expert evidence as well. They wanted some formula that should take into account the healings at Lourdes, and the healings which occur in Christian Science, and the conversion of drunkards, and the results obtained by good parents in the management of morbid-minded children, and the legions of cases that were cured of their faults, not by any treatment that they could reasonably call suggestion, but by the rude awaking of the will, or even by punishment. They would never get that formula so long as they kept inside psychology; nor, if they did get it in psychology, would "the man in the street" accept it from them. "For he is inclined," continued Mr. Paget, "to think that psychology neither is, nor ever will be, a complete science. You cannot, he says, truly state the influence of the mind on the body in terms of the natural sciences. Once you begin to use the old phrases of dualism you must give up, he says, the phrases of naturalism: you cannot so much as mention mind, and will, and consciousness, without you acknowledge certain philosophical principles which may be forgotten or denied with impunity by psychology. He is of opinion that psychology is apt to be unprincipled, especially when she gives herself to experimental researches; that she watches and analyses the working of mind before she has made up her own as to the true nature of ours. Always he insists that he is more than a succession of states of consciousness: always he hangs on, somehow, to idealism. In spite of all his free-thinking he still takes a theological view of the case; he will not let himself be explained away as a byproduct of natural forces; he is more than unscientific, he is anti-scientific; he appeals from science to faith. Where psychology uses the Greek word psyche he uses the English word soul; and if she says that he does not know what he means by that word, he hits back at her with a Tu quoque. He cannot think of hypnotism without fear lest it may root up with the tares the wheat also; and he finds no significance in the words subliminal consciousness. For he is a philosopher; and there is no more ancient feud than that which is between real philosophy and real science. That is why the man in the street is so taken with Christian Science. It offers him, with both hands, any amount of metaphysical phrases and any amount of religious poetry-all of it bad, and most of it false; still, it is acceptable to a man of his temperament. Of course, if psychology were a science in that sense in which we use the word of chemistry and astronomy, this discussion would have no reference to popular opinion. But, as things are, we find ourselves, in practice, between two opposed armies, and not in perfect agreement with either of them. If we go over to the experimental psychologists we turn our backs, to my thinking, on a

great many valid and essential facts of human experience; if we go over to popular opinion we turn our backs on another set of no less valid facts, and find ourselves further than we like from science, and nearer than we like to Christian Science. We are a neutral country, and we pay for that privilege. We have no standing army; but the neighbouring countries in time of war claim the right to march through our territory, and they do a good deal of damage to the harvest. Public opinion is in urgent want of some clear statement of the difference between those diseases where mind, as a therapeutic agent, has what may be called a good opening, and those where it has none. Such a statement, carefully prepared and widely circulated, would be an excellent safeguard against the ill deeds of Christian Science, and would be in accordance with the best traditions of our profession."

The Value of Hypnotism.

Dr. R. H. Cole said that 20 years ago, when a house physician, he first tried to hypnotise patients. Later he went to Paris and attended the Salpêtrière and Bernheim's cliniques, but was grievously disappointed in what he saw. He now returned to the consideration of the matter perhaps less sceptical than formerly, but with his belief still somewhat shaken. He had come to the conclusion that hypnotic suggestion might be powerful for good and for evil, and that only medical men (and those special physicians and not men in general practice) should be trusted with its use. In his experience of mental diseases he had only seen it do good in one insane patient. It had never had any effect in his experience upon people with fixed delusions, but it would cure dipsomania. Drugs should not be neglected when suggestion was being used. The medical profession should use all methods of healing short of actual spiritual ministrations, which were the business of the clergyman. Suggestion, Dr. Cole believed, acted through definite physical channels and was a proper method of treatment, but the physician was not concerned with faith in the spiritual sense.

Dr. J. F. Woods said that he had practised hypnotism for 17 years and had treated 4000 cases, and he described a few of them in which he had obtained remarkable results. One was that of a woman with severe asthma and delusions that she was going to be cut to pieces who was cured by suggestion at one sitting and had kept well since. Another case of severe soiatica which had resisted every line of treatment for eight months was also cured rapidly. He did not find it necessary to induce hypnotic sleep. His custom was to place the patient in an armchair and tell him to relax his muscles and compose his thoughts. He would sometimes stroke the forehead or epigastrium and when the patient was quite comfortable he would make suggestions of tranquillity, warmth, and restfulness. He would then leave the patient for half an hour and on returning often find him in a self-induced hypnotic sleep. Dr. Woods proclaimed himself an enthusiastic supporter of the forms of treatment under discussion.

Mr. H. W. ARMIT brought back the discussion to more general lines. He said that Christian Science and other allied irregular practitioners were seriously trespassing upon the province of medical men who ought, therefore, to examine carefully the principles underlying psychic treatment. It was noteworthy that a stranger would almost always influence a patient's mind more than a familiar practi-tioner, and it was therefore better that suggestion should be given by an unknown medical man than by the patient's usual attendant. During the debate many terms such as Mind, Will, Subconscious Mind had been used, of which nobody really knew the meaning, but because a thing was inexplicable it did not follow that it should be neglected when a valuable method of treatment had been founded upon it. Suggestive treatment was really very old, as witness the time-honoured method for the cure of functional aphonia. It was a disastrous thing that the public wished to credit the practi-tioners of hypnotism with "a special gift of God." In illustration Mr. Armit quoted the case of a man suffering from asthma, in which an unexpected cure had been effected by a hypnotic practitioner, who subsequently found himself in the embarrassing position of being regarded as a special agency of divine beneficence. That sort of attitude must be discouraged. The only way to stop the use of suggestive therapeutics outside the profession was for members of the profession themselves to employ them fearlessly and quietly.

Dr. E. L. ASH gave the conclusions drawn from his personal experience in hypnotism. He considered that something more than verbal suggestion was wanted, which something might be the induction of hypnotic sleep or a combination of suggestion with material means of treatment. He believed that the latter was the more valuable course to adopt. It was, indeed, adopted in a half-hearted manner by every medical man who gave a placebo and told his patient that it would relieve his condition, but it should be done thoroughly and earnestly after a study of the individual indications in each case. Drugs, massage, and electricity were the adjuncts to treatment which he adopted particularly. Genuine hypnotism (the state of somnambulism) was unsatisfactory in practice. Only a small proportion of cases could be hypnotised, and these, in his experience, did no better than those treated by simple suggestion. He quoted two cases of nocturnal enuresis, one of which he had failed to cure by hypnotism whilst the other was cured by suggestion, and a case of blepharo-spasm which had been cured by suggestion with light massage on the eyelids, although a similar case treated only by suggestion had not been relieved. He submitted the following conclusions: (1) That suggestion should be much more commonly used as a routine method of treatment; (2) the advantages of aiding suggestion as a therapeutic measure by the induction of the hypnotic state seem to be very doubtful; (3) that suggestion should be chiefly used as an adjunct to ordinary therapeutic methods, and regarded from this point of view is likely to ultimately prove to be one of the most valuable measures at our disposal; and (4) that the restriction of the practice of suggestive therapeutics to the narrow limits of a specialty, to the disregard of general medicine, is both unscientific and

Dr. W. H. BLAKE followed by describing a series of cases in which as a general practitioner he had used hypnotism with the utmost benefit. He insisted that it was impossible to ignore the value of mental therapeutic measures when such cases had been actually seen, and he urged the medical profession to master its principles. His most remarkable cures had been effected in a case of asthma for which the patient was accustomed to drench himself unavailingly with drugs, and in a severe case of dipsomania.

in a severe case of dipsomania.

After some remarks by Mr. HAYDN BROWN.

Dr. CLAYE SHAW wound up the discussion by a few wise remarks, in the course of which he said that the Harveian Society was bound to admit the testimony which it had heard that hypnotism and suggestion were valuable agents in the cure of definite disease.

BACTERIOLOGICAL INVESTIGATIONS ON SOME MODERN MOUTH DISINFECTANTS.

BY DR. EUG. PIASECKI.

(From the Hygienic Institute of the University of Lemberg, Austrian Poland.)

THE city of Lemberg being alarmed by a severe epidemic of scarlet fever in the year 1908 the local sanitary authorities endeavoured to discover what preventive measures might be commonly adopted both in families and schools. Professor Dr. Raczynski drew the attention of the sanitary commission to formamint, the use of which had been strongly advocated by Dr. Meredith Young 1* and others. It was accordingly resolved to submit this, and some other new drugs, to bacteriological investigation. Entrusted with this task by Professor Dr. Kucera (to whom I am greatly indebted for many kind suggestions), I decided to limit my inquiry to two newly-introduced methods—namely, antiseptic lozenges (formamint) and antiseptic spray (pyocyanase).

Although the nature of the great majority of infectious diseases which threaten the child of school age is not known, there is no doubt about the bulk of contagion being transmitted through the mouth or nose. This seems to be the case even with the acute exanthemata, where, amongst other proofs, we see inflammation of mucous membranes precede the cutaneous symptoms. A really effective method of disinfection of the mouth, nose, and pharynx must be, therefore, considered as a most powerful preventive against a whole series of maladies.

Amongst methods hitherto in use for this purpose I omitted gargling, in the first place, because it does not affect the pharynx, at least as it is commonly used and as it can be taught to school children; and, in the second place, because very exact investigations of Röse 2 have shown that really strong gargles irritate the mucosa too much to be used for hygienic or preventive purposes. Swabbing and douching are said to act very strongly, but, on the other hand, they require too much practice to be greatly employed outside hospitals. On the contrary, lozenges seem to be an ideal method from the purely technical point of view. Dr. Young 1 has insisted on their merits so exhaustively that there is nothing to be added. The process of spraying, mentioned above, presents several well-marked advantages, two of which are that it requires no special training and covers very accurately the whole surface of both mouth and pharynx.

A. - FORMAMINT.

If we omit purely clinical observations, there has not been as yet much written on the subject. Rheinbold and Daus simply state that "formamint saliva" (i.e., saliva taken immediately after sucking of formamint tablets) develops a distinct bactericidal action; moreover, they do not care to give more exact quantitative calculations than those expressed by the terms "many" and "few" colonies. Jaenicke published Loewenthal's observations, according to which five formamint tablets destroyed active movements in the case of bacillus fusiformis, spirillum sputigenum, and endamœba buccalis. Reissner was the first who endeavoured to estimate numerically the action of the drug. He gargled with tepid pump water and poured it afterwards into a sterilised glass vessel, from which a sample was taken on a loop of platinum wire and inoculated on agar plates. Colonies were counted after 24 hours' cultivation at the ordinary (!) temperature. This procedure was repeated at intervals of from two to ten minutes after sucking formamint tablets, the number of which was not stated. Three experiments of this kind showed reduction of the initial number of colonies to one-half after two minutes and to oneseventh after from five to seven minutes. Reissner also prepared several tables illustrating the action of formamint in vitro on different species of bacteria; as he does not, however, mention the method used, the description of this part of his work is incomplete. Meredith Young's article 1 on the subject will be remembered by the readers of THE LANCET; I shall therefore give only a brief summary of the results as far as they touch the bacteriological side of the question. Two experiments with formamint were made on a young healthy clerk whose bacterial flora amounted to 300,000 microbes on a swab with which the mucosa of the throat was touched on several consecutive "control" days. In the first of these the swab taken immediately after one tablet had been sucked was sterile; after ten minutes there were 35 microbes on the swab; and after 30 minutes there were 150 microbes on it. In the second experiment the man sucked two formamint lozenges—one every half-hour—and then gargled with sterilised water. The results were that the samples taken from the anterior faucial pillars showed 7500 colonies before the experiment and 80 colonies after it, while the samples from the posterior pharynx showed 965 colonies before the experiment and 80 colonies after it.

As to the details of the method, the swabs used were of constant size; they were brought into contact with the mucosa under possibly constant amount of pressure; each of them was immediately packed, labelled, and sent for examination to Professor S. Delépine who, after dilution of the initial sample in sterilised water, not only counted all colonies grown on agar plates at 37° C., but also determined the number of colonies belonging to some particular species, including staphylococcus pyogenes aureus, staphylococcus pyogenes albus, streptococcus, and micrococcus tetragenus.

Proceeding to new investigations, the first question I endeavoured to answer was, To what extent, and in how strong concentration does formaldehyde (i.e., the disinfecting component of the drug) act in vitro as a disinfectant in human saliva? For this purpose I made a series of experiments from Oct. 3rd to 15th, 1908. I collected in a sterile glass from 6 to 8 cubic centimetres of my own saliva, and inoculated a sample of it in the manner described further on. Then I distributed the saliva in several tubes, 1 cubic centimetre in each, and added to each of them a different dose of formalin, except for one tube in which the saliva was left in the natural state. All the tubes were immediately

The superior figures throughout the article refer to the bibliography

placed in a thermostat at 37°C., and samples therefrom were taken at certain intervals and inoculated. To prevent evaporation of the formaldehyde each tube was covered with a closely fitting glass cap. In two instances where I gave a formamint tablet instead of formalin, it was quickly pulverised in a sterile mortar and the tube was thoroughly shaken before taking each sample. Inoculation was executed by diluting 0.05 cubic centimetre of saliva in 5 cubic centimetres of physiological salt solution, and taking there-from another 0.05 cubic centimetre for addition to ascites fluid, which mixed with an equal portion of agar liquefied at 45° C., was poured out on plates and kept at 37° C. for 24 hours.

In order to be able to compare the value of the disinfecting action in different experiments I took the number of colonies in 1 cubic centimetre of saliva in the first proof (before adding formalin) as = 100, and then calculated percentage numbers, showing the increase or diminution of the microbes, as had already been done by Röse.² The results in "control" tubes (without formalin) were as follows:—

TABLE I.

				At the ginnin	g.	10 min. later.	•	30 min	١.	60 min. later.
Oct.	5th	•••	•••	100	*****	198		106		132
••	7th	•••	•••	100	*****	93	•••••	152	••••	167
••	15th	•••	•••	100	•••••	61		93		51

The absolute numbers at the beginning were respectively: 12,576,000, 30,976,000, and 35,360,000 colonies from 1 cubic centimetre of saliva.

The figures from tubes to which different doses of formalin were added are ranged below according to decreasing quantity of the disinfectant :-

				* In	a tabi	let.						

As repeated microscopical investigations showed that the character of the microbic flora in my saliva was fairly uniform, somewhat marked differences between the figures from Oct. 5th and, say, 15th are to be attributed chiefly to differences in the antiseptic action of the saliva itself (Clairmont 7). Experiments with formamint tablets were made by adding one tablet (=0.025 formalin) to 1, or to 5 cubic centimetres of saliva, and they show an inferior antiseptic action as compared with corresponding quantities of pure formalin. The real volume of saliva in which a formamint tablet is dissolved during actual sucking in the mouth can be estimated to be 25 or 30 cubic centimetres. Accordingly, the first experiment on Oct. 7th (0.001 formalin in 1 cubic centimetre of saliva) would be nearest the natural conditions; but the figures-104, 43, 90, 39-ought to be somewhat increased (see above), and the antiseptic action, as estimated from experiments in vitro, would, therefore, not even equal an average of 40 per cent. in the first hour.

Repeated tests on the living subject, carried out on the same lines as in Dr. M. Young's experiments, gave contradictory results, which is easily understood, taking into account the rather weak action of the drug and the somewhat rough method. It is, for instance, impossible to ensure even an approximately constant amount of pressure of the swabs on the mucosa. I adopted, therefore, a more exact method—namely, that of Miller-Röse (Röse), which I modified in some details. With two healthy individuals (Δ = the author, and B = a school-boy 15 years of age), the bacteria contained in the saliva "normally" (i.e., without any drugs) were investigated, six or seven samples being taken at certain intervals during two or three hours. The whole daily curriculum of both individuals was carefully regulated, and especially during the test period of two or

three hours all the appreciable conditions were kept equal. As taking meals and speaking aloud are known to reduce the amount of microbes in the cavity of the mouth each individual abstained from both eating and speaking during the whole period. With A the first sample was taken three-quarters of an hour after breakfast, and with B one and a half hours after tea, both meals being carefully regulated as to both quality and quantity. This proof is to be found under C ("control") in each series. The second proof followed after 15 minutes, and as it corresponds in the "formamint" series to proofs taken immediately after sucking the first tablet, it is designated as 0. The following intervals are—15, 30 minutes, 1 hour, 2 hours, and 3 hours after 0.

Miller-Röse's method of taking proofs, which consists in gargling with an "indifferent" liquid (peptone, Witte, 1.0, chloride of sodium 5.0, and distilled water 1000.0), was, after two comparative experiments, found to be not more exact than a materially simpler way, which I therefore adopted. Proofs were taken by spitting about two cubic centimetres of saliva into a sterile tube, care being taken to avoid all forcible action of the respiratory or chewing muscles. From this I took 0.05 or 0.01 cubic centimetre of saliva and diluted it once or twice in physiological salt solution until the agar and ascites plate inoculated therewith contained from $\tau \delta_0$ th to τJ_0 th of the initial material. The plates were kept at 37°C. for 24 hours, and the colonies were counted afterwards with the help of a microscope and a counting plate. This procedure limits, it is true, our investigation to the anterior portion of the cavity of the mouth, but, on the other hand, as in the "formamint series" the tablets were held just in the same portion during sucking, there is full evidence that our method detected the action of the drug in favourable conditions. The table below shows the results expressed (in the same way as above with experiments in vitro) in percentage figures :-

Average	. 100	60	3 107	88	109	100	94

The absolute figures, relating to column C, are: 92,800,000, 49,200,000, 27,500,000, 17,500,000, and 50,700,000.

By these results Röse's conclusions are corroborated, according to which simple evaluation of bacteria-rate "before" and "after" taking a drug would not be sufficiently exact for our purpose. With Person A, for instance, we see that the amount of microbes is rapidly growing during the observation period; any somewhat weak antiseptic action would, then, not be detected, the results show-ing us more microbes "after" in spite of the drug. Now, if we compare the above "normal" averages with corresponding averages from days in which the drug was taken, we shall detect the microbicidal action even where it simply consists in limiting the growth of bacteria-rate.

Now I proceeded to the formamint series. The first type

of them (carried out with A only) consisted in experiments made in exactly the same way as above, with the unique difference that during the whole interval between C (control) and 0-proof two formamint tablets at once were sucked and swallowed. The results are to be seen in the table below:—

TABLE V.

Date.	C.		m m		15 min		30 min	1 h.	2 h.	3 h.	1	Average 0-2 br.

" 11th	100	•••	144	•••	126	•••	-	 3 65	 2470	 _	•••	776
,, 14th	100		44	•••	88		378	 255	 0	 _	•••	193
Average	100	•••	159	•••	144	•••	239	 677	 1254			445

The absolute figures relating to column C are 4,672,000, 5,375,000, 400,000, 5,700,000, and 900,000.

Compared with the average figures from the "normal" series, the above table shows the following differences, the mode of calculation being as follows. I took each of the average numbers of Table III. as = 100, and calculated for such case the relative value of corresponding average figures in Table V. The differences (- = below 100, + = above it) represent the amount of microbicidal action in the given moments of the observation period. For instance, Table III., column 0, average 171. If we take it = 100, the corresponding figure of Table V. (159) will amount to 93. Difference, -7Conclusion: the drug developed, immediately after sucking, a microbicidal action of 7 per cent. -i.e., killed 7 per cent. of the bacteria. C, \pm 0; 0 minute, \pm 7; 15 minutes, \pm 42; 30 minutes, \pm 1; 1 hour, \pm 49; 2 hours, \pm 147; average (from 0 to 2 hours), \pm 52. After a short period of antiseptic action, there is, then, an absolute disappearance of this action about half an hour after swallowing, followed by increased growth of bacteria, which amounts, after two hours, to nearly 150 per cent of the normal rate. This somewhat paradoxical result can be understood when compared with similar phenomena observed by Röse 2 after gargling with some liquid mouth disinfectants. This author demonstrated that some strong disinfectants lower the vitality of the epithelium of the mucous membrane, and thereby produce, after a short period of a decreased rate of bacterial growth, conditions more favourable to bacterial growth than before. I felt, therefore, authorised to consider the dose of two tablets (at least for A) as too large a one, and gave, in the subsequent series, smaller doses (one tablet each), repeated at intervals of half an hour. Tablets were held in the mouth as long as possible (by A for 15 minutes and by B for from 5 to 8 minutes), the second inoculation was made, as above, immediately after the first dose, consecutive inoculations, on the contrary, inasmuch as they coincided with taking of tablets (i.e., at 30 minutes, 1 hour, and 2 hours) before the latter, so that instantaneous effects of formamint are registered in the column 0 only. A took during three hours six tablets, and B took during two hours four tablets. The results with A (calculated as above) are shown below:—

TABLE VI.

Date.	C. 0	min. 15 min.	30 min.	1 h.	2 h.	3 h.	Average 1-3 h.

				—			
Average	100	183 125	. 167	231	282	692	279

The absolute figures relating to column C are: 9,600,000, 1,600,000, 2,300,000, 800,000, and 1,200,000.

The differences from the "normal" series (calculated as above) are: $C, \pm 0$; 0 minute, + 6; 15 minutes, - 50; 30 minutes, - 31; 1 hour, - 49; 2 hours, - 44; 3 hours, - 15; average (0 - 3 hours - 34—i.e., bactericidal action does not, on the average, rise higher than 34 per ent., whereas its maxima amount to 50 per cent. If we consider that there were, on the average, at the end of the observation period, about 13,000,000 bacteria in 1 cubic centimetre of saliva still alive, such a degree of disinfection can hardly be of any practical value. Besides, we see at the end of some series (Nov. 19th, Dec. 9th) considerable growth of microbes, from which it seems to follow there can be seems to follow there can be seems to follow there can be seemed to seem the difficulties to beat, as colonies of more resistant species (spore-producing bacilli) formed everywhere a vanishing minority, and were often totally absent. Neither was there any evidence of the so-called "selective" action (by which certain species are killed or have their growth limited and others are spared); the flora of the last plates in a series in the colonies (aspecially the superficial ones) cultivated from his saliva was that of micrococcus catarrhalis, alike in the times of perfect health and during slight catarrh of the times of perfect health and during slight catarrh of the times of perfect health and during slight catarrh of the whole growth of micrococcus catarrhalis more frequently in

of them (carried out with A only) consisted in experiments | mucosa irritation, by which bactericidal action finally turns made in exactly the same way as above, with the unique | into its reverse.

TABLE VII.

Person	B.												A٧	erage

Averag	e	100		106		92		93		84		51		92

The absolute figures relating to column C are 39,200,000, 35,000,000, and 12,700,000.

The differences from the average "normal" figures (calculated as above) are: $C, \pm 0$; 0 minute, + 61; 15 minutes, - 14; 30 minutes, + 5; 1 hour, - 23; 2 hours, - 49; arraye, - 2: an inconstant, and, on the average, very weak action

The reason of the difference shown by B, as compared with A, seems to consist, at least partially, in the fact mentioned above, that B was unable to hold the tablets in his mouth, as a rule, even half as long as A, whereby naturally the duration of the drug's action on the contents of the mouth was considerably limited. This was the case, though I never omitted reminding B of the necessity of tablets being held as long as possible. There is every probability that with younger children the duration of tablet sucking would be still shorter in accordance with the smaller degree of will power and the smaller degree of ability to concentrate the attention. It follows, then, that just within those age limits where formamint should do the greatest services we are entitled to anticipate still weaker effects.

Rosenberg sproved, it is true, the presence of formaldehyde in the blood after a formamint tablet had been sucked; thus one lozenge might act even after being completely swallowed. If, however, the concentration of aldehyde in the blood were sufficient to be taken into account, its action would be detected.

in the later stages of our observation period.

To the above conclusions an objection might still be made -namely, that bacteria which were left alive might belong to some more resistant species. This I partially prevented by using ascites-agar. We know that on ascites-agar a series of more delicate species (micrococcus meningitidis, gonococcus, pneumococcus, &c.) find better conditions of growth, whereas ordinary, more resistant saprophytes grow thereon worse than on pure agar. Besides, I proceeded to definition of species. Unfortunately, we do not possess as yet methods suited to define the species of each colony on fairly densely inoculated plates. I could, therefore, do no more than (1) direct my attention when counting the colonies constantly to their morphological characters; and (2) examine microscopically a series of proofs belonging to colonies which seemed to represent different species. With Person A I found in the series with six tablets from Nov. 8th in all the plates an overwhelming majority of streptococcus pyogenes. There were also a few colonies of bacilli belonging to the subtilis group and a species of Gram-positive micrococcus. In a series of the same kind from Nov. 19th on all plates only streptococcus was found, except one (0 minute), in which, on four colonies investigated, two belonged to pneumococcus. With Person B in the series from Jan. 8th (four tablets) in all plates almost exclusively micrococcus catarrhalis was found. Of other species we saw a few pneumococci, streptococcus pyogenes, and very small numbers of saprophytes (namely, Grampositive large micrococci, and very rarely bacilli belonging to the subtilis group). As far as can be seen from the aspect of colonies, the bacterial flora of the other series must have been of much the same composition. There is, consequently, no reason to believe that the bactericidal factor had any particular difficulties to beat, as colonies of more resistant species (spore-producing bacilli) formed everywhere a vanishing minority, and were often totally absent. Neither was there any evidence of the so-called "selective" action (by which certain species are killed or have their growth limited and others are spared); the flora of the last plates in a series had the same character as that of the first or "control" plate. As to Person B, the aspect of the immense majority of the colonies (especially the superficial ones) cultivated from his saliva was that of micrococcus catarrhalis, alike in the times of perfect health and during slight catarrh of the nose. It is conformable with the observations of Arkwright,9

the noses of persons suffering from catarrh than in normal noses.

Conclusions.—1. Formaldehyde develops in vitro, in certain concentrations, a strong bactericidal action on the flora of the saliva of healthy individuals. In concentrations, however, which can be considered as nearest to natural conditions with formamint tablet sucking, its action is weak. 2. Investigations carried out in the living subject give similar results. In the first place, after a large single dose of formamint (two tablets) there is a transitory bactericidal action, followed by a considerably augmented growth of bacteria in the cavity of the mouth. In the second place, with smaller, frequently repeated, doses (single tablets at one and a half hours' interval) the growth of bacteria is no doubt lessened, but only to an extent to which hardly any practical value can be attributed.

B.—PYOCYANASE.

Emmerich and Loew 10 saw that in mixed bouillon cultures which contained mostly bacillus pyocyaneus, the sediment as well as the superficial film (both composed of bacteria) disappeared after long standing. They attributed this to bactericidal ferments, acting not only upon the species which produced them. Further investigations corroborated this supposition. Old bouillon cultures of bacillus pyocyaneus, separated from bacteria and their residues and brought by evaporation to one-tenth of their initial volume, gave a liquid containing several proteolytic enzymes (nucleases); these observers named it pyocyanase. According to quite recent investigations (Schapiro 11) a number of bacterial species can be divided into three groups in accordance with their susceptibility to the action of pyocyanase. The liquid acts strongly on bacillus diphtheriæ, bacillus pseudodiphtheriæ, xerosis, vibrio choleræ, streptococcus pyogenes, pneumococcus, gonococcus, meningococcus, bacillus fæcalis alkaligenus, and bacillus dysenteriæ (Shiga). An intermediate position is occupied by bacillus typhi, bacillus paratyphi A, staphylococcus pyogenes aureus, micrococcus tetragenus, and bacillus pneumoniæ (Friedländer). A weak action is developed against bacillus coli, bacillus paratyphi B, and bacillus enteritidis; whereas bacillus pyocyaneus, bacillus fluorescens, and proteus find even conditions of growth in pyocyanase.

From these observations great advantages might be expected for the problem of so-called internal disinfection. The means which hitherto have been used for this purpose in addition to their bactericidal effects, produced more or less pronounced injurious effects on the tissues of the human body, whereas the bacteriolytic enzymes, being free from this defect, may be applied without fear in proper concentration to the mucous membranes.

Clinical and bacteriological investigations on spraying with pyocyanase in diphtheria (Zucker, 12 Muehsam 13) encourage the tree of it together with antidiphtheritic serum. In an epidemic of grippe caused by micrococcus catarrhalis, and observed in infants at a clinique in Vienna, Escherich and Jehle 14 proved that from 24 to 48 hours after pyocyanase had been instilled into the nose there was a total absence of micrococcus catarrhalis. Jehle 14 administered pyocyanase by instillation in the course of an epidemic of cerebro-spinal meningitis to a series of patients as well as to healthy "contacts" in whose naso-pharyngeal cavity meningococci were found. The meningococci disappeared after one or two applications of pyocyanase.

It is obvious, then, that in several diseases in which the mouth and the nasal cavity are unquestionably the only door of infection we may expect favourable results from pyocyanase as experience has shown. I do not refer here to the technical details of the investigations mentioned above, because they seem to be quite irreproachable, and in this respect they form a contrast to much that has been written about formamint. The question I proposed to myself was, Can the growth of bacteria in the cavity of the mouth in healthy persons be limited by the application of pyocyanase in a degree suited for general hygienic and preventive purposes?

The choice of method did not cause any difficulties. In order that they might admit of comparison with the previous investigations of the action of formamint observations were made on the same person A, and, as a basis for the appreciation of bactericidal action, the same series of "control" experiments was used, the results of which are shown above

in Table III. In the usual course of experiments the following changes ensued, as compared with the "formamint series." Immediately before the second inoculation (marked on the table with 0), I made, exactly in the manner described by the inventors, 20 sprayings with pyocyanase in two series of ten sprayings each, with an interval of five minutes between them, the utmost care being taken to cover equally the whole cavity of the mouth. Each compression of the bag was as complete as possible. The excess of pyocyanase left in the mouth was spat out. A curious phenomenon connected with these cases was intense salivation, which lasted over an hour or so. The colour of the two or three first samples of the saliva (i.e., until 30 minutes after spraying) was greenish. The results (calculated as above) are ranged below.

TABLE VIII.

```
Date. C. 0 min. 15 min. 30 min. 1 h, 2h. 3 h. Average 0-3 hr.

Dec. 19th ... 100 ... 11 ... 79 ... 106 ... 33 ... 29 ... — ... 4291 ... 897

Average ... 100 147 249 123 161 298 1642 $83
```

The absolute figures relating to column C are: 7,500,000 1,650,000, 1,100,000, 2,700,000, and 5,925,000.

The differences (calculated as with formamint) from the "normal" series shown in Table III. are as follows: $C, \pm 0$; 0 minute, -14; 15 minutes, -1; 30 minutes, -49; 1 hour, -65; 2 hours, -41; 3 hours, +101; average (0 to 3 hours), -9. In spite of considerable oscillations, the bactericidal action of the liquid was therefore from 30 minutes to 2 hours after the application, a fairly distinct one; in some series, however (Dec. 20th and 23rd), the decrease of the bacteria rate turns during the third hour into its reverse; we have again an "irritation," just as in the series with a large single dose of formamint (see above).

These results lead me to suppose that, for Person A at least, we shall be perhaps nearer the optimum of pyocyanase action when giving, during the observation period of three hours, two smaller doses. In five ensuing experiments I accordingly made immediately before the second inoculation ten sprayings only, whereas ten other sprayings were executed at the middle of the observation period—i.e., one and a half hours after the second inoculation (between the fifth and sixth inoculations). The results are shown below:—

Αve	rage	 100	 93	 151		149		165	 154		187		146

The absolute figures relating to column C are: 15,525,000,7,900,000, 6,200,000, 12,050,000, and 13,975,000. Calculated as with formamint, the differences from the normal series are: $C \pm 0$; 0 minute, -46; 15 minutes, -40; 30 minutes, -39; 1 hour, -66; 2 hours, -70; 3 hours, -77; average (0 to 3 hours), -66. The rate of the growth of bacteria in the cavity of the mouth was accordingly less by from 39 to 77 per cent. (on the average by 66 per cent.), as compared with observations during which no drug was applied. Contrary to Table VIII., the action shows here a fairly constant increase towards the end of the observation period. Moreover, if we compare the figures obtained, not to speak about formamint, with those given by other mouth disinfectants which were recommended after investigation by sufficiently exact methods (e.g., mouth washes, Röse 2), we must consider pyocyanase, when used in the way described, as the strongest of them.

As to definition of species, microscopical investigations were made on plates from Dec. 24th, 31st, and Jan. 3rd, in the first of these series the bulk of the bacteria being streptococci; about a quarter of the colonies on all the plates belonged to micrococcus catarrhalis. On the two other days

(Person A had then a slight pharyngitis) an immense majority of micrococcus catarrhalis was found; of other species there was only pneumococcus. A "selective" action of pyocyanase (stronger on some than on other species) was not detected.

We had, then, just as in the preceding observations, a bacterial flora of fairly uniform composition, belonging to species which resist disinfectants less strongly. Schapiro¹¹ assigns streptococci and pneumococci to the least resistant group as regards pyocyanase; he does not, however, mention micrococcus catarrhalis, about which we conclude from Jehle's dissertation 14 that it is easily killed by pyocyanase. I endeavoured, therefore, to calculate the bactericidal power of pyocyanase in relation to that microbe, and for that purpose used Schapiro's method. To an ascites-agar culture of micrococcus catarrhalis (cultivated from the mouth of Person A) I added 2 cubic centimetres of bouillon and made an emulsion of bacteria with the help of a loop of platinum wire. From this I transferred, with a pipette, 0.2 cubic centimetre to a tube containing 2 cubic centimetres of pyocyanase, and placed the latter, together with a "control" tube (2 cubic centimetres of pure bacteria emulsion), in a thermostat at 37°C. I then inoculated samples from both tubes at certain intervals. As to inoculations, 0.1 cubic centimetre of well-shaken liquid was diluted in 5 cubic centimetres of physiological salt solution, and from this mixture the same quantity was again diluted in the same manner. From this second dilution 0.1 cubic centimetre was transferred to ascites fluid which was, together with agar liquefied at 45° C., poured out on plates. The results (counted after 24 hours' cultivation at 37° C. and calculated for 1 cubic centimetre of liquid) are given below :-

TABLE X.

•		15 min.	40 min.	1 h.	24 hr.
Bouillon emulsion	•••	4,925,000	7,700,000	7,225,000	Impossible
10% of emulsion pyocyanase		200,000 (= 4 %)	275,000 (= 3 %)	175,000 (= 2 %)	

The stock now investigated proved a little more resistant than the species ranged by Schapiro in his first group. On the other hand, it is to be considered far more sensitive to the action of pyocyanase than Schapiro's second group. This fact, together with the results of our experiments in the living subject in which micrococcus catarrhalis was not destroyed by pyocyanase in the course of three hours, lead us to conclude that, in spite of the results obtained by Escherich and Jehle with infants, we cannot expect a similar marked action of pyocyanase upon micrococcus catarrhalis in adults.

Conclusions.—1. Pyocyanase sprayed into the cavity of the mouth in a large single dose may sometimes, after a transitory period of bactericidal action, cause increased growth of microbes. 2. When sprayed in smaller, repeated doses pyocyanase develops a higher bactericidal action than any other mouth disinfectant which has hitherto been recommended after exact investigation. Before we can recommend pyocyanase, however, for daily use by healthy persons more extensive investigations are indispensable. Such a recommendation must be withheld until the perfect innocuity of the liquid for the mucous membrane of the human mouth is proved. Circumstances have unfortunately prevented me from carrying out such investigations.

From carrying out such investigations.

THE PROPOSED FORMATION OF A SPECIAL CIVIL MEDICAL SERVICE IN INDIA.

AT a meeting of the members of "the independent medical profession" of the Bombay Presidency held on Sept. 8th at Bombay under the auspices of the Bombay Medical Union and the presidency of Sir Bhalchandra Krishna, L.M., a memorial unanimously adopted was directed to be forwarded through the proper authorities to the Secretary of State for India (Lord Morley), dealing with the question of the present position of the independent practitioners of India and their claims that all civil medical appointments at present controlled by the Government of India should be thrown open to native practitioners, and that what they consider the present monopoly of these posts by officers of the Indian Medical Service should be done away with. The memorial, which is a lengthy one, has evidently been evoked by Lord Morley's recent despatches to the Viceroy of India, in which the former foreshadowed that no further increase in the personnel of the civil side of the Indian Medical Service would be approved, and that a strong effort should be made by the authorities in India to employ medical practitioners locally to fill appointments where suitable candidates were forthcoming. There can be no doubt that Lord Morley's pronouncement evoked feelings of keen satisfaction amongst native Indian practitioners, and their feelings are now echoed in the memorial which they have drawn up. The request for recognition, coming as it does from the educated Indians of Bombay Presidency, will obtain the sympathetic consideration of the India Office. Nevertheless, we regret to note that the memorialists have thought fit to embody what can only be considered as an indictment of the pioneer medical service of India—the Indian Medical Service—and this is not only unjust but tactless, as over 90 per cent. of the native practitioners who now demand to share in the medical appointments in India owe their very existence, their teaching, and their licences to practise in India, to the very service they now arraign.

By the medical profession of the United Kingdom little is known or understood of the ways and means whereby the medical administration of India is carried out. Medical education of the native practitioners is carried out by the medical colleges. These institutions are financed and controlled by the State, and in the majority of instances education is free. The appointments to professorships and lectureships in these colleges are made by the Government after due consideration of the names of suitable candidates put forward by the Director-General of the Indian Medical Service. Likewise appointments to civil surgeoncies are made, and sanitary and public health appointments are made on nominations put forward by the Sanitary Commissioner to the Government of India, who is also an officer of the Indian Medical Service. On the other hand, appointments on the military side are made by the Commander-in-Chief from nominations put forward by the Principal Medical Officer of His Majesty's Forces in India. Members of the independent practitioner class have no representative to foster their interests on the headquarter staff of either the civil or military supreme government. But as a matter of fact, neither the civil nor military medical service has any medical representative on the Viceroy's Council, and medical and sanitary questions have no prominent position, as they are included amongst a shoal of other matters in the "portfolios" of the "Home" and "Army" members. Sanitation and allied sciences suffer accordingly. These facts are stated in the memorial from Bombay, which brings home the inadequate representation of the profession generally in the government of a country where matters of health should occupy a very much more important position than they are allowed to do at present.

The memorialists suggest certain lines along which their proposed scheme of reform might be directed. The more important of these point out that all appointments in the civil medical profession should be thrown open to proved merit and ability wherever found, and that the sons of the soil, meaning the native practitioners, should have an equal chance with the Indian Medical Service to compete for such appointments, their fitness being based on merit, qualifications, and other credentials alone, and not on any class membership or consideration of supposed service exigencies. They recommend

that the Indian Medical Service be turned into a purely military service, and that a special, purely civil, medical service be created for civil purposes. They desire that multiple professorships should be abolished and that the holders of professorships should not be allowed to hold appointments as well on the staffs of hospitals. The financial side of their proposed reforms if accepted is also embodied, and they anticipate an annual saving to the State of nearly £200,000 per annum. The names of the signatories of the memorial have not been included in the copy of the memorial sent to us, but we gather that they represent the native practitioners of Bombay alone, and we may remark that this Presidency in medical matters is by no means typical of the conditions found elsewhere in India. The native practitioners in Bombay include many Parsi gentlemen of the highest professional attainments, many of whom at present fill important hospital appointments in the Presidency with marked ability, but it is not understood from the memorial whether these gentlemen are desirous of serving elsewhere in Government appointments if so selected.

The memorial raises in a very distinct form certain difficult questions in connexion with our Indian rule in general, and with the Indian Medical Service in particular. An efficient Indian Medical Service must be one of the most important assets in the government of India, and every pains must be taken to keep it at its high level. But there is not an officer in that small service who does not recognise the justice as well as the expediency of making full use of native talent and of rewarding it proportionately. I anticipated in the memorial is problematical. The vast saving

THE INTERNATIONAL CONFERENCE ON LEPROSY.

THE report framed by Dr. Arthur Newsholme and Sir Malcolm Morris as the delegates of His Majesty's Government to the International Scientific Conference on Leprosy, held at Bergen in August, has been issued as a Parliamentary Six representatives from British colonies also attended. The report sets out in a succinct form the conclusions arrived at as the result of the deliberations at the Conference. They are as follows :-

Onference. They are as follows:—

1. The second International Conference on Leprosy confirms in every respect the resolutions adopted by the first International Conference of Berlin, 1897. Leprosy is a disease which is contagious from person to person, whatever may be the method by which this contagion is effected. Every country, in whatever latitude it is situated, is within the range of possible infection by leprosy, and may, therefore, usefully undertake measures to pretect itself.

2. In view of the success obtained in Germany, Iceland, Norway, and Sweden, it is desirable that other countries with leprosy should preceed to isolate their lepres.

3. It is desirable that thepers should not be permitted to follow certain occupations which are particularly dangerous in respect to the contagion of leprosy. In every country and in all cases the strict isolation of leprous beggars and vagrants is necessary.

4. It is desirable that the healthy children of lepror should be separated from their leprous parents as soon as possible, and that these children should remain under observation.

5. An examination should be made from time to time of those who

children should remain under observation.

5. An examination should be made from time to time of those who have lived with lepers by a competent physician.

6. All theories on the etiology and the mode of propagation of leprosy should be carefully examined to ascertain if they accord with our knowledge of the nature and the biology of the bacillus of leprosy. It is desirable that the question of the transmissibility of leprosy by insects should be elucidated, and that the possibility of the existence of leproid diseases among animals (rats) should receive early study.

7. The clinical study of leprosy induces the belief that it is not incurable. We do not at present possess a certain remedy. It is desirable, therefore, to continue the search for a specific remedy.

The British and Colonial delegates to the Conference had a meeting at which they drew up additional resolutions, which in their judgment embody—when read in conjunction with official resolutions of the Bergen Conference—the line of administrative policy which it is desirable to adopt for the prevention of leprosy throughout the British Empire, so far as local circumstances permit.

The resolutions of the British and Colonial delegates are in the following terms :-

1. Leprosy is spread by direct and indirect contagion from persons suffering from the disease. The possibility that indirect contagion may be effected by fleas, bugs, lice, the itch parasite, &c., has to be borne in mind. Leprosy is most prevalent under conditions of personal and domestic uncleanliness and overcrowding, especially where there is close and protracted association between the leprous and non-leprous.

2. Leprosy is not due to the eating of any particular food, such as fish.

3. There is no evidence that leprosy is hereditary; the occurrence of several cases in a single family is due to contagion.

4. In leprosy an interval of years may elapse between infection and the first recognised appearance of disease. It is a disease of long duration, though some of its symptoms may be quiescent for a considerable period and then recur.

5. The danger of infection from leprous persons is greater when there is discharge from mucous membranes or from ulcerated surfaces.

6. Compulsory notification of every case of leprosy should be enforced.

enforced.
7. The most important administrative measure is to separate the to the most important administrative measure is to separate the leprous from the non-leprous by segregation in settlements or asylums.

8. In settlements home life may be permitted under regulation by

In settlements home life may be permitted untor regulation by
the responsible authorities.
 The preceding recommendations, if carried out, will provide the
most efficient means of mitigating the leper's suffering and of assisting
in his recovery, and at the same time will produce a reduction and
ultimate extinction of the disease.

This statement is signed by Dr. Newsholme, Sir Malcolm Morris, Dr. B. J. Bull (Commonwealth of Australia), Dr. C. F. K. Murray (the Cape of Good Hope and Natal), Dr. George Turner (the Transvaal and Orange River), Sir Allan Perry (Ceylon), Dr. J. E. Godfrey (British Guiana and the Bahamas), and Mr. B. Glanvill Corney (Fiji).

THE CONTROL OF MEDICAL EDUCATION IN THE UNIVERSITY OF LONDON.

Proposed Formation of a Board of the Faculty of Medicine .-Amendment of the Scheme by the Senate. - Meeting of the Faculty of Medicine.

IT will be remembered that last March a memorandum was presented to the Faculty of Medicine of the University of London by Professor E. H. Starling proposing the formation of a Faculty Board of a convenient size which should be endowed with the present advisory powers of the Faculty, and which might be expected to be invested ultimately with executive authority. The scheme, which has been published in full in THE LANCET, rested in brief the following arguments. At present the Faculty of Medicine is only represented on the Senate by the the medical subcommittee of the Academic Council, and one of whom at present is a member of the External Council. The initiation of action in the internal affairs of the University, so far as concerns medicine, is practically in the hands of the three representatives of the Faculty, for the two medical representatives of Convocation on the Senate are members of the External but not of the Academic Council, which has the power of formulating representations to the Senate concerning each Faculty, and through which each Faculty must approach the Senate on the "internal" affairs with which it it concerned. Professor Starling submitted that three men could not adequately represent a Faculty of 400 members, whilst he recognised that so large a body was too unwieldy as a whole to assume administrative functions. Whilst no alteration could be effected in the mode of appointment of the Boards of Studies in each Faculty or of the Academic Council, it was within the power of the Faculty to delegate its advisory functions to a Faculty Board and "to request the Senate to regard its delegates on this Board as the Faculty itself and as the chief advisory body in Medicine." At the meeting of the Faculty of Medicine on March 12th, adjourned to March 26th, on the recommendation of Professor Starling and Dr. Leonard Hill, it was unanimously recommended that such a Board should be appointed in accordance with the scheme which we have already published.1 This provided for a board of some 30 members, with the Dean and Secretary of the Faculty as chairman and vicechairman respectively, and with liberal representation of all the Boards of Studies and of the Faculty as a whole, including all the members of the Faculty of Medicine who are also members of the Senate, as well as the two medical representatives of Convocation on the Senate and the representative of the University on the General Medical Council. It must be admitted that this body could easily be made representative of all the schools. The quorum of this Faculty Board was to be 10, and it was further recommended that the Board be empowered to report to the Senate on any subject within the purview of the Faculty through either the Academic or the External Council, provided that

¹ THE LANCET, March 20th, 1909, p. 861.

on the requisition of 10 members any question should be reserved for the consideration of the Faculty as a whole. The Senate was also requested to take no action on the principal medical affairs of the University until it had received a report from the proposed board upon the question at issue. These recommendations were subsequently sent up to and approved by the Academic Council, but were disapproved by the External Council. The Senate considered them upon Oct. 20th, and after some debate it was resolved that a Board of the Faculty of Medicine should be appointed, but the recommendation putting forward the Faculty's scheme for the constitution of such a Board was defeated in favour of the following amendment which subsequently became a substantive resolution.

That a Board of the Faculty of Medicine be appointed on the lines of the existing Boards of the Faculties of Arts and Sciences and with similar functions, and that it be referred to the Faculty of Medicine to prepare and submit to the Senate a scheme for the constitution of the Board accordingly.

We may mention that the Faculty Boards referred to in the resolution consist of the Dean of the Faculty, all members of the Faculty who are also members of the Senate, one representative of each of the Boards of Studies in the Faculty of Arts, and two in the Faculty of Science, and other members of the Faculty not exceeding five whom the Faculty may appoint. The Boards are appointed annually by their respective Faculties, they require no quorum for their deliberations, and their function is solely to report to their Faculties. It is plain, therefore, that the effect of the amendment was to suggest the establishment of a Board with functions in no way resembling those direct advisory powers which the Faculty of Medicine desired for its proposed Board.

The resolution of the Senate in the above terms was considered by a meeting of the Faculty of Medicine held at the University on Nov. 1st, the Dean, Dr. Sidney Martin, being in the chair. After some discussion it was resolved, on the motion of Professor STARLING, seconded by Dr. F. J. SMITH, that the question be referred to the committee now sitting to consider the report of the Faculty to the University, and consisting of the Dean of the Faculty, Mr. H. J. Waring, Dr. Leonard E. Hill, Professor E. H. Starling, Dr. H. A. Caley, Dr. H. L. Eason, Dr. W. P. Herringham, Dr. H. Batty Shaw, Dr. E. I. Spriggs, Dr. J. Kingston Fowler, Dr. H. G. Turney, Dr. F. de Havilland Hall, Dr. Cecil Wall, Mr. Peyton Beale, Mr. F. C. Wallis, Mr. W. H. Clayton-Greene, Professor G. D. Thane, Professor Peter Thompson, and Miss Cock.

At this meeting of the Faculty of Medicine the com-

mittee which was appointed on July 9th, 1909, to consider and report upon the following resolution of the Senate-

That each of the Faculties be invited to report to the Senate through the Academic Council such changes, if any, in the constitution of the University as they desire to recommend in the interests of the Faculty

which had been referred to the Faculty by the Academic Council, presented their report containing the following recommendations :-

1. That the medical degrees of the University of London should be pen only to those students who are students in the schools of the

University.

2. That all medical questions affecting the University should be submitted to some such body as the Faculty Board recommended by resolution of the Faculty of Medicine on March 26th, 1909.

3. That all Boards of Studies in medical subjects shall be committees of the Faculty and appointed by the Faculty after receiving a report from the Faculty Board.

4. That the Faculty Board shall report to a body of the character of the present Academic Council, who shall have executive power in all academic matters not involving finance.

These recommendations were adopted by the Faculty in its report to the Senate.

The other business considered by the Faculty at this meeting was as follows:

Changes in the constitution of the Boards of Studies with which the Faculty is concerned were made for 1910 on the recommendation of the boards themselves.

Preliminary Medical Studies .- The Board to remain as at present.

Intermediate Medical Studies. - Professor P. Thompson* to go off; Mr. J. E. Purvis to go off; Dr. J. Cameron* to be added.

Advanced Medical Studies .- The Board to remain as at

Destisiery.—Mr. W. A. Maggs* to go off; Mr. C. S. Tomes to go off; Dr. J. W. Pare* to be added; Mr. M. A. Smale to be added.

Hygiene and Public Health .- Dr. J. F. W. Tatham to go off; Dr. E. C. Seaton to be added; Dr. D. S. Davies and Dr. H. F. Parsons, examiners in State Medicine, to be

Physiology and Experimental Psychology.—Dr. J. Mellanby to be added

Human Anatomy and Morphology.—The Professor of Anatomy at King's College to be added if and when he becomes a teacher of the University; Professor P. Thompson to be added.

* Those marked with an asterisk are teachers of the University.

The DEAN reported that he had received a letter from the Secretary to the Royal Commission now sitting to inquire into the working of the University, dated August 2nd, 1909, asking for the appointment of representative members to bring the views of the Faculty of Medicine before the Commission, and also members to express the views of the minority if any existed. The appointment of representatives was postponed until after the reports of the Boards of Studies should be received. These were directed to be submitted to the above committee of the Faculty appointed on July 9th.

The meeting then terminated.

Looking Back.

FROM

THE LANCET, SATURDAY, Nov. 5th, 1831.

THE TREATMENT OF CHOLERA.

Mr. Kennedy ably exposes the manner in which efficient remedies lost confidence by their inappropriate administration in unsuitable conditions of the disease, and in which other remedies obtained a surreptitious notoriety in cases which would have recovered without their use. He ably, and to our mind most satisfactorily, vindicates the employment of blood-letting, and then proceeds "the consideration of a discriminative system of medical management,"—in the first place, giving a short description of the disease itself, which, in correspondence with the necessities of medical treatment, and the course the attack in general pursues, he divides into two varieties; one the protracted or severe, the other the rapid or violent. The protracted type consists of two stages:—

"First Stage.—The patient complains of feeling of anxiety, or of uneasiness at the pit of the stomach. After some time nausea supervenes, and the uneasiness changes into a feeling of heat or pain. To these symptoms succeed vomiting and purging and prostration of strength. The evacuations at first consist of the common contents of the alimentary canal; afterwards of a fluid like rice-water. Occasional cramps are felt in the limbs. The pulse is small and rather quick. The countenance of the patient is somewhat shrunk, and the features appear sharper than natural."

If the disease be left to itself, or if it continue to advance in spite of the remedies that may have been used, the symptoms increase in severity, and the patient comes to suffer from-

"Violent cramps in the upper and lower limbs, and at times in the muscles of the chest and belly. The cramps, in general, are not constant; they recur at short intervals in paroxysms. The vomiting and purging are severe. The coldness of the skin has increased much; it feels moist, and is of a bluish colour about the face, hands, and feet. The palms and soles of the latter appear corrugated, as if they had been steeped in water. The pulse is barely, or not at all, to be detected in the wrists and temples. The countenance is ghastly, and expressive of great anxiety. There is distressing thirst, and burning heat or pain in the region of the stomach or bowels."

If the disease be still uncontrolled, it will pass into the second stage.

"Scond Stage.—Under the increasing debility the vomiting, purging, and cramps, are subsiding or have disappeared. The patient lies in a state of helpless exhaustion, and is almost incapable of making the slightest movement. He is apparently insensible, but as his senses remain unimpaired to the last, he may be roused to say 'yes' or 'no.' The pulse is gone, and even the action of the heart is extremely feeble. The surface of the body is deadly cold. The breathing is oppressed, or scarcely perceptible, and the countenance is quite cadaverous."

In the treatment of the first stage, the primary object of the physician should be to allay the cramps, vomiting, and purging. For this purpose, not one remedy, but a combina-tion of remedies should be adopted. The WARM-BATH, bleod-letting, and a large dose of calomel and laudanum, are to be instantly prescribed. When the cramps have subsided,

1

26

20

ŋ

Ę.

DRY heat should be applied by surrounding the patient's body with hot blankets, sand-bags, &c.

The treatment of the second stage will be very different. During the first there is vital power, and high spasmodic action, but in the second the patient is in a state of real exhaustion, and would sink under the measures adopted for the first. Even the warm-bath is dangerous to life now, and must be avoided.

In the second stage there are two indications, 1st, to remove deadly coldness; 2nd, to remove the great debility. For the first, recourse must be had to DRY heat: for the second, to stimulants, such as ether, ammonia, brandy.

The rapid type now comes to be considered, as in many instances the attack is desperate, the patient suddenly falling down, perhaps insensible. There is little visible attempt at reaction. The pulse disappears at the wrist, the heat declines. In these cases, cramps, vomiting, and purging, are either completely absent, or exceedingly slight in their existence. Two stages may still be formed;

1. That of apparent debility; 2. That of real debility. For the treatment of these varieties, we must adopt the author's own words :-

"The chief remedial measure is blood-letting, and here its use is founded upon the fact, that, for a certain space of time after the commencement of the attack, the resources of the constitution are not to be measured by the external symptoms."

(At the end of the remainder of the quotation, which we cannot here transcribe for lack of space, the Editor states, "We shall quote no further. To the work itself we refer the anxious practitioner.")

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 7785 births and 3786 deaths were registered during the week ending Oct. 30th. The annual rate of mortality in these towns, which had been equal to 12 9, 12 2, and 12 0 per 1000 in the three preceding weeks, were again equal to 12 0 in the week under notice. During the first four weeks of the current quarter the annual death-rate in these towns averaged only 12.3 per 1000, and in London during the same period the rate did not exceed 11 · 9 per 1000. The lowest annual rates of mortality recorded in the 76 towns last week were 6 · 7 in Cardiff, 6.9 in Walthamstow, 7.0 in Wolverhampton and in Bury, and 7.1 in Hornsey; the rates in the other towns ranged upwards, however, to $17 \cdot 5$ in Oldham, $17 \cdot 6$ in Great Yarmouth, and $18 \cdot 0$ in Newport (Mon.). In London the recorded death-rate last week did not exceed 11.9 per 1000. The 3786 deaths in the 76 towns last week exceeded by but 14 the low number in the previous week, and included 293 which were referred to the principal epidemic diseases, against numbers declining steadily from 849 to 311 in the nine preceding weeks; of these 293 deaths, 110 resulted from diarrhoea, 57 from diphtheria, 42 from whooping-cough, 38 from measles, 30 from scarlet fever, and 16 from "fever" (principally enteric), but not one from small-pox. The 293 deaths from these epidemic diseases last week were equal to an annual rate of 0.9 per 1000, which was lower than the rate from these diseases in any previous week of this year. No death from any of these epidemic diseases was registered last week in Norwich, Rochdale, Reading, York, or in five other smaller towns; the annual death-rates therefrom ranged upwards, however, to 3.4 in Burnley, 3.7 in West Bromwich, 4.0 in Merthyr Tydfil, and 7.6 in Hanley. The deaths attributed to diarrhosa in the 76 towns, which had declined in the nine preceding weeks from 675 to 141, further fell last week to 110, and were fewer than in any week since the end of July; the highest death-rates from this cause in these towns last week were 1.5 in Burnley, 2.2 in West Bromwich, and 2.3 in Hanley. The deaths referred to diphtheria, which had been 51 and 46 in the two previous weeks, rose last week to 57, and caused death-rates equal to 1·1 in Hudders-field, 1·3 in Merthyr Tydfil, and 1·7 in Barrow-in-Furness; this disease also caused 18 deaths in London and its suburban

preceding weeks, rose to 42 last week, and were proportionally most fatal in Swansea. The 30 fatal cases of scarlet fever showed a further decline from recent weekly numbers; and the 16 deaths referred to "fever" showed a considerable decline from the numbers in recent weeks, but included 2 each in Portsmouth, Leeds, and Newcastle-on-Tyne. The number of scarlet fever patients under treatment in the Metropolitan Asylums and London Fever Hospitals, which had been 2810 and 2799 at the end of the two preceding weeks, had further declined to 2743 on Saturday last; 284 new cases of this disease were admitted to these hospitals during last week, against 371 and 345 in the two preceding weeks. The Metropolitan Asylums Hospitals contained 2 small-pox patients on Saturday last. Of the 1107 deaths registered in London last week, 193 were referred to pneumonia and other diseases of the respiratory system, against 167 and 174 in the two preceding weeks, but were 36 below the corrected average number in the corresponding week of the five years 1904-08. The causes of 27, or 0.7 per cent. of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death registered during last week were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Salford, Leicester, and in 56 smaller towns; the 27 uncertified causes of death in the 76 towns last week included 8 in Liverpool and 6 in Birmingham.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 787 births and 462 deaths were registered during the week ending Oct. 30th. The annual rate of mortality in these towns, which had been 12.8 and 13.1 per 1000 in the two preceding weeks, declined again to 12.9 in the week under notice. During the first four weeks of the current quarter the annual death-rate in these Scotch towns averaged 12.7 per 1000, and exceeded by 0.4 the mean rate during the same period in the 76 large English towns. The annual death-rates last week in these Scotch towns ranged from 8.0 in Aberdeen and 11 · 4 in Paisley, to 18 · 4 in Perth and 18 · 8 in Greenock. The 462 deaths from all causes in the eight towns last week showed a decline of 8 from the number in the previous week, and included 34 which were referred to the principal epidemic diseases, against 45 and 54 in the two preceding weeks. These 34 deaths were equal to an annual rate of 1.0 per 1000, against a mean rate of 0.9 from the same diseases last week in the 76 English towns. The 34 deaths from these diseases in the Scotch towns last week included 10 from diarrhosa, 9 from measles, 6 from scarlet fever, 4 from diphtheria, 4 from whooping-cough, and 1 from "fever," but not one from small-pox. The deaths attributed to diarrhosa, which had been 15 and 28 in the two preceding weeks, declined last week to 10, and were fewer than in any week since the end of March last; 4 were returned in Glasgow and 2 in Leith. The 9 fatal cases of measles exceeded the number in any recent week, and included 8 in Glasgow. Of the 6 deaths from scarlet fever, 5 occurred in Glasgow. The fatal cases of diphtheria, which had been 12 and 11 in the two preceding weeks, declined last week to 4, of which 2 were returned in Edinburgh. The 4 deaths from whooping-cough included 2 both in Glasgow and in Edinburgh; and the fatal case of "fever" occurred in Glasgow. The deaths referred to diseases of the respiratory system in the eight towns, which had been 57 and 84 in the two preceding weeks, declined again to 68 last week, and were 19 below the number in the corresponding week of last year. The causes of 9, or 1 9 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 0.7 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of rather more than a million, 614 births and 359 deaths were registered during the week ending Oct. 30th. The mean annual rate of mortality in these towns, which had districts, and 6 in Manchester and Salford. The 38 fatal cases of measles showed a slight increase, and caused been equal to 1.5 in West Bromwich, Wallasey, and Burnley, and to 3.8 in Hanley. The deaths from whooping-cough, which had been 27 and 28 in the two

mean death-rate during the same period did not exceed 12 · 3 in the 76 largest English towns, and 12 · 7 in the eight principal Scotch towns. The annual death-rate during last week was equal to 18.6 in Dublin, 19.1 in Limerick, 19.2 in Cork, 15.6 in Belfast, and 15.7 in Londonderry; the mean rate in the 16 smallest Irish town districts last week was equal to 13.9 per 1000. The 359 deaths from all causes in the 22 town districts last week showed an increase of 34 upon the number in the previous week, and included 26 which were referred to the principal epidemic diseases, against numbers declining from 42 to 22 in the four preceding weeks; these 26 deaths were equal to an annual rate of 1.2 per 1000, against 1.0 in the previous week; in the 76 English towns the rate from the same diseases last week did not exceed 0.9 per 1000. The 26 deaths from these epidemic diseases in the Irish towns last week included 12 from diarrhosa, 10 from whooping - cough, 2 from "fever," and 1 each from measles and diphtheria. but not one either from scarlet fever or small-pox. The 12 deaths from diarrhoea in the 22 towns last week corresponded with the number in the previous week, and included 3 in Dublin, 3 in Belfast, and 2 in Waterford. The 10 fatal cases of whooping-cough showed an increase of five upon the number in the previous week; 5 occurred in Belfast, 3 in Limerick, and 1 each in Dublin and Waterford. Of the 2 deaths referred to enteric fever 1 each The 60 deaths was returned in Dublin and in Lisburn. referred to pneumonia and other diseases of the respira-tory system last week in the 22 towns showed an increase of 10 upon the number in each of the three pre-The causes of 19, or 5.3 per cent., ceding weeks. of the deaths in these Irish towns last week were not certified by a registered medical practitioner or by a coroner; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 0.7 per cent., and in the eight Scotch towns the proportion was 1.9 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified: —Staff-Surgeons: F. H. Nimmo for three months' study at West London Hospital, lent, to reside at Greenwich College; P. T. Nicholls to the Victory. Surgeons: J. R. A. Clark-Hall to the Excellent; and G. G. Vickery to the Victory, additional, for disposal.

ROYAL ARMY MEDICAL CORPS.

Lieutenant William E. Marshall is seconded for service with the Egyptian Army (dated Oct. 14th, 1909).

Major M. P. C. Holt, D.S.O., has been appointed specialist in advanced operative surgery, 3rd (Lahore) Division. Major R. F. E. Austin, from Chatham, has been appointed to India.

THE ROYAL ARMY MEDICAL CORPS COLLEGE

The course for Captains on promotion to Major has begun at the Royal Army Medical College, Millbank, S.W. The course of instruction will be extended over a period of nine months and some 50 officers will attend. It is understood that the first three months will be devoted to lectures and laboratory instruction in military hygiene and tropical medicine at the College, the second three months to postgraduate courses in the London hospitals, and the last three months to specialist's work connected with either hygiene, bacteriology, advanced operative surgery, ophthalmology, midwifery and diseases of women and children, dentistry, or venereal diseases and dermatology. Examinations will be held at the end of each three months.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel Harris has been appointed an Honorary Surgeon to H.E. the Viceroy, vice Lieutenant-Colonel Perry. Major Heard, on his return to India from leave, has been appointed Professor of Midwifery in the Lahore Medical College. Major Hugh Ainsworth, at present Officiating Medical Adviser, Patiala State, has been appointed Professor of Ophthalmic Surgery in the Lahore Medical College. The services of Colonel Carruthers and Captain Cazalay are replaced at the disposal of the Commander-in-Chief. The replaced at the disposal of the Commander-in-Chief. The maintains a convalescent home (70 beds), to which over services of Captain Roberts are replaced at the disposal of 1000 patients are admitted annually. To carry on this great

the Army Department, and those of Captain Young are placed temporarily at the disposal of the Eastern Bengal and Assam Government for employment in the Sanitary Department. Captain Holmes has been appointed Civil Surgeon at Quetta. Major E. C. Macleod, Agency Surgeon, is granted one year's leave. Lieutenant Zorab is permitted to resign the service from Sept. 26th, 1909.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Supplementary List: The undermentioned to be Lieutenants (on probation):—Edward Andrew Gregg (dated July 30th, 1909), and Arthur Henry Habgood (dated Sept. 22nd, 1909).

TERRITORIAL FORCE.

Royal Army Medical Corps.

London Mounted Brigade Field Ambulance: Captain William Peart Thomas, from the 2nd London (City of London) Field Ambulance, Royal Army Medical Corps, to be Captain (dated Sept. 27th, 1909).

1st London (City of London) General Hospital: Brigade Surgeon-Lieutenant-Colonel and Brevet Colonel Charles Edward Harrison, C.V.O., retired pay (late Grenadier Guards) to be Lieutenant-Colonel (dated Oct. 19th, 1909).

Attached to Units other than Medical Unics .- Lieutenant Ashley Bird to be Captain (dated April 1st, 1908).

For Attachment to Units other than Medical Units .- John Walter Pridmore to be Lieutenant (dated Sept. 21st, 1909).

Correspondence.

"Audi alteram partem."

THE ROYAL HOSPITAL OF BARTHOLOMEW.

To the Editor of THE LANCET.

SIR,—A few months since public attention was directed to the needs of St. Bartholomew's Hospital by a conference at the Mansion House between the Lord Mayor, the treasurer of the hospital, and the masters of the leading City guilds, with reference to the financial position of the institution. At that meeting Lord Sandhurst, the treasurer, explained the exact state of affairs, and the Lord Mayor read the following letter which he had received from Colonel Sir Arthur Bigge:

Marlborough House, Pall Mall, S.W.

Mariborough House, Pall Mall, S.W., April 6th, 1909.

My Dear Lord Mayor.—I am directed by the Prince of Wales to inform you that, as President of St. Bartholomew's Hospital, he has lately had an opportunity of learning from Lord Sandhurst, the treasurer, that there is now an annual deficit of about £12,000 in the working of the hospital, due in a large measure to payment of interest on a capital debt of approximately £170,000. His Royal Highness me to say that he has received this information with much regret, as he would view with grave concern the necessity for in any degree curtailing the work of what is the only general hospital in the City boundaries. His Royal Highness sincerely trusts that funds may be raised to prevent the possibility of such an unfortunate contingency.

Yours very truly,

The Right Hon, the Lord Mayor.

ABTHUR BIGGE.

For various reasons, but in particular as it was desired not to clash in any way with the annual collection of the Hospital Sunday Fund, it was decided to postpone making a general appeal until the autumn. The time has now arrived when it has become necessary to take steps to meet the grave situation with which St. Bartholomew's is faced, and we desire to urge its unique claims to public sympathy and

support.

For nearly 800 years St. Bartholomew's Hospital has carried on, on its present site, a great work: firstly, in the alleviation of the sufferings of the sick, maimed, and diseased poor; and secondly, in the training of medical practitioners whose services in after life are of incalculable benefit to humanity, rich and poor alike, all over the world. From time to time the accommodation of the hospital has been increased to meet the demands upon it, and there are now 680 beds. On an average 8000 patients are admitted to its wards in each year, while some 130,000 persons are treated in the out-patients' department. The hospital also

work involves an expenditure of about £75,000 a year, and until recently the revenues of the hospital were sufficient for its maintenance and the general public was not asked to contribute in any way, but owing to the gradual expansion of expenditure consequent upon the advance of medical and surgical science, and to the reduction of the available income by some £9000 a year, due to certain charges for interest and sinking fund in connexion with the acquisition of additional site, there is now a deficit of about £12,000 per annum. The capital debt upon which interest is payable is approximately £170,000, of which sum £50,000 was borrowed to meet current obligations, mainly in connexion with the recent structural additions.

While acknowledging the generous response accorded to the special appeal started in 1904 for rebuilding purposes we feel very strongly that the claims of St. Bartholomew's Hospital have hitherto not been fully realised by the public, and it has consequently lacked support proportionate to its needs and to the great benefits it confers. In again referring to the fact that the hospital has been maintained for generations, unaided by the public, we would mention incidentally that it has not participated in the benefactions of King Edward's Hospital Fund for London or the Hospital Sunday and Saturday Funds.

A special fund has been started to liquidate the capital debt and thereby reduce the annual deficit, and we very earnestly appeal for contributions for this purpose and for annual subscriptions towards the general maintenance of the hospital. Cheques may be addressed to the Right Hon. the Lord Mayor, Mansion House, E.C., or to the Lord Sandhurst. Treasurer, St. Bartholomew's Hospital, London, E.C.

THE INFLUENCE OF DIET ON THE THYROID GLAND.

To the Editor of THE LANCET.

SIR.—I observe with interest that increasing attention is being paid by clinicians to the influence of diet on the thyroid gland. For example, we find that Dr. Leonard thyroid gland. For example, we find that Dr. Leonard Williams in his interesting address published in THE LANCET of Oct. 30th expresses the following opinion: "The explanation of all the numerous meat-excluding dietaries is based on the fact that their apostles and disciples suffer from diminished activity of the thyroid gland upon which meat fouds are known to act so as still further to diminish its activity." The italics are mine, and with your permission I would like to comment on the statement here made. It is possible that the views which have been recently expressed by some writers as to meat being a "depressant of thyroid activity" have their origin, to some extent, in the results of the investigations on this subject which I have published in the last few years. I think it important, therefore, to raise

a word of caution as to the too general adoption of the view that a meat diet "depresses" thyroid activity.

The fact is that a meat diet is primarily a stimulant of the thyroid gland, and my observations have, I think, shown that this stimulating effect may be continued throughout the life of the animal. The stimulating effect is revealed by an increase in the size of the gland or by a change in the microscopic appearances of the gland, or by both of these conditions. In the later stages of life, or in the second generation of animals, the effect is more frequently the reverse, the microscopic appearances of the gland indicating a marked impairment in its functional activity. From the clinical point of view it is, I think, important for practitioners to bear in mind not only the "depressant" properties of meat in mind not only the "depressant" properties of meat in relation to the thyroid gland to which increasing attention is now being made, but also to its "stimulating" properties as described above. I have previously drawn attention to this. There are conditions—e.g., tuberculosis—in which a diet which contains an excessive amount of protein is of special value in treatment; in my opinion the beneficial effects of the dietetic treatment in these cases are to a great extent the result of the special influence of that diet on the thyroid gland. On the other hand, there are conditions-e.g., gout in which the administration of a diet which contains little protein is of special value, and I think that clinicians are right in accepting the view that this favourable result is in an important degree attained through the influence of that diet on the thyroid gland.—I am, Sir, yours faithfully,

Edinburgh, Oct. 30th, 1909.

CHALMERS WATSON.

ECZEMA AND STAPHYLOCOCCUS VACCINE.

To the Editor of THE LANCET.

SIR,-In THE LANCET of Sept. 25th last I wrote on this same subject. In that letter I was myself the patient, and the argument for the use of staphylococcus vaccine in eczema would have been dismissed by anyone who considered that the disease described was that of a staphylococcus infection of the skin, a disease already recognised by Savill and others as bearing a close resemblance to eczema. Since the above case there has been under my care a boy, aged 16 years, who was suffering from acute eczema of a very pronounced type, and this boy has become completely cured in five weeks, the treatment—specifically for the diseasebeing solely the staphylococcus vaccine. The case shall be described and the reasons for regarding it as an ordinary case of severe acute eczema will be seen to be quite strong. The contention that it was cured by staphylococcus vaccine and the deduction that some cases of acute eczema are due to general staphylococcus infection will in that case have to be admitted.

The boy became ill with spots on the face on Sept. 10th; by the 12th they had extended greatly, and when I saw him on the 14th the condition was as follows. The right external ear was covered with branny scales of eczema; the external meatus was discharging freely; the sides of the face and chin were so covered with scab and rash that the patient was an object of curiosity to the beholder and unpleasantly self-conscious of the fact. The beholder and unpleasantly self-conscious of the fact. rash covered the whole of the front of the trunk so thickly as to give at a little distance a rosy-red appearance; the front of the thighs and legs down to the tibial tubercles, where the rash was more sparse than on the trunk; both elbow flexures, the front of the forearms and the palmar aspect of the hands and fingers; two or three fingers on either hand were bandaged on account of the "weeping." The injections of vaccine were all made into the arms; they were commenced on Sept. 15th and were continued to Oct. 23rd. They were given as follows in millions:—Sept. 15th, 100; 18th, 100; 22nd, 250; 25th, 500; 27th, 500; 29th, 750; Oct. 2nd, 1000; 9th, 1000; 23rd, 750. Very little local pain followed the injections and no constitutional disturbance. The periods chosen for the injections were according to the duration of the local induration at the site of the injections and the progress of the case. When this progress was arrested a fresh injection followed.

The progress of the case was uninterrupted. On Sept. 21st, 22nd, and 23rd the patient came to consult me on account of great pain in the penile urethra after passing urine. The

wrine passed was very acid, but I did not find any crystals. He did not come until after the last date of the pain, and this did not recur after benzoate of soda was given. This pain I ascribed to irritation of the urethra from the passage of crystals of uric acid or urate of soda. By Oct. 2nd the patient was well except for the ear and a few spots on the chin and pubis. On the 9th the only evidence of the persistence of the rash was a triangular patch amongst the public hair, and on the 23rd he was quite well except for a few discrete spots over the publs. I propose to continue the injections for another six weeks. The diagnosis was based. firstly, upon the appearance of the rash and its character of accumulating scaly scabs and weeping; secondly, on the character and reaction of the urine; and, thirdly, on the fact that the boy's mother had suffered from two wellmarked attacks of acute eczema during her lifetime.

I am, Sir, yours faithfully, G. W. DAVIS, M. D., B.S. Durh. Sidcup, Oct. 25th, 1909.

FAIR-HAIRED JEWS.

To the Editor of THE LANCET.

SIR,—In reading your report in THE LANCET of Oct. 30th of Dr. Leonard Williams's paper, "To Redress the Balance," I note he refers to "the fair skin and the red hair which long residence in northern climes has conferred upon some Jewish families." Dr. Williams is evidently unaware that this type of Jew is common in the East. Professor Ripley in his work "The Races of Europe" says: "The rufous tendency in the Oriental Jew is emphasised by many observers" (p. 394). On the same page he quotes Beddoe as suggesting that a cross with the blonde Amorites may account for the phenomenon. To myself it appears to be one of the most significant facts in the part played in history by the Jewish nation that Palestine is situated at a meeting-point of the three great ethnic divisions of the world; and the Jews, whether in their origin or by absorp-tion of individuals from neighbouring races, have affinities with "all people that on earth do dwell."

I am, Sir, yours faithfully, J. S. MACKINTOSH, M R.C.S. Eng., L.R.O.P. Lond. Hampstead, Oct. 30th, 1909.

THE BIRTHPLACE OF SIR THOMAS BROWNE.

To the Editor of THE LANCET.

SIR, -As a Norfolk man I was naturally interested in your annotation (Oct. 30th, p. 1299) on the Norfolk and Norwich Hospital, but was not prepared to find the statement that Sir Thomas Browne was born in Norwich. I believe there is very little doubt he was born in London. In Dr. Johnson's life of Sir Thomas Browne it is stated that he was born "in the parish of St. Michael-in-Cheapside on Oct. 19th, 1605; his father was a merchant of ancient family at Upton in Cheshire; of the name or family of his mother I find no account." He settled in Norwich in 1636.

I was in Dublin a few weeks ago, and the "jarvey" who was driving me told me that the Nelson monument in Sackville-street was erected to the memory of a distinguished brishman named Lord Nelson who was born in Dublin. I was not surprised at this information coming from the owner of an Irish jaunting-car, and one is now getting quite familiar with inaccuracies in certain political speeches, but one hardly expected to find anything but "the truth, the whole truth, and nothing but the truth" in THE LANCET.

I am, Sir, yours faithfully, H. LITTLEWOOD.

LONDON HOSPITALS AND SCHOOL CHILDREN.

To the Editor of THE LANCET.

STR.—Under the above heading in to-day's Times a proposed arrangement between the London County Council and various hospitals is outlined. May I point out in regard to St. George's Hospital that the children to be seen are to be selected necessitous cases who are unable to provide adequate treatment for themselves, either through a private general

practitioner or otherwise, there being a double safeguard that only necessitous children are treated-firstly by as inquiry by the London County Council, and secondly one by the hospital almoner, for whom the hospital reserves this right. I trust you will be good enough to insert this, as this distinction makes a great difference, and the statement as appearing to-day may give rise to serious misunderstanding.

I am, Sir, yours faithfully,

A. WILLIAM WEST,

Treasurer and Chairman, St. George's Hospital, S.W.
St. George's Hospital, S.W., Nov. 3rd, 1909.

THE BREAD PROBLEM AT BUDAPEST.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

THE OUTCRY AGAINST BAD AND DIRTY BREAD .- THE OLD PARIS MUNICIPAL BAKERY .- THE NEW MODEL MUNI-CIPAL BAKERY AT BUDAPEST .- HOW THE WORKMEN ARE BATHED AND CLOTHED BEFORE MAKING BREAD.

On the occasion of the Sixteenth International Congress of Medicine the most elaborate measures were taken at Budapest to show the foreign members whatever progress had been achieved from the medical or sanitary points of view. The faculty of medicine, the clinics, the operatingrooms, the hospitals, the charitable institutions, the bacteriological and other institutes, the asylums, the disinfecting station, the waterworks, the sewers, the schools and crèches, the public baths, and many other establishments were thrown open to the visitors. All that Budapest had to show proved very interesting, and many of these social and public services were admirably organised, but the greatest sympathy was naturally evoked by certain work being done in Budapest that has not been attempted elsewhere. The town of Budapest has undertaken to supply the inhabitants with clean, wholesome, and cheap bread. Model bakeries exist in many places, but the only general municipal bakery I have ever visited is that of Paris, and it is a very amail undertaking when compared with the bakery which the municipality of Budapest has built, and which was inaugurated the week before the Medical Congress met.

Many years ago now I described the Paris municipal bakery. It is situated in the Rue Scipion, near the Boulevard des Gobelins, and now its only purpose is to supply bread to the municipal hospitals. There was, however, a time when there were depôts in the public markets so that the ordinary inhabitants of Paris might buy the municipal bread, which was very generally found to be better made, cheaper, and purer than that sold in many of the shops. This custom prevailed from 1856 to 1870, and the municipal quartern loaf was always a halfpenny cheaper than the price of bread as by law established. It is known that in France, ever since the great Revolution, bread is taxed; that is to say, the authorities decide from time to time at what price bread must be sold, and the tax or tariff varies, of course, according to the price of wheat. After the siege of Paris the municipal bakery ceased to self its bread to the public, and only baked 14,000 kilogrammes daily, which is consumed for the most part in the hospitals and asylums. The municipal supply, therefore, no longer comes into competition with the general baking trade.

At Budapest some six years ago the poorer sections of the community made many complaints about the bread. It was badly made and insufficiently nutritious. The press took up the question and a cry arose for a better bread-supply. The municipality, to whom it was pointed out that other towns were better served and that at Vienna the bread was not so dear and more wholesome, took up the entire question, and finding that the bakers were not at all inclined to build proper and clean bakeries and were indifferent to the protests of the public they determined to set up a model municipal bakery. By municipal competition the private bakers would be either driven out of the trade altogether or compelled to produce in decent premises wholesome and clean bread. The public should not be allowed to suffer any longer through the self-interest of the baking trade. A model bakery, therefore, has been built at a cost of £25,448. It may, in further explanation of this action, be added that there is no special law in Hungary on bakeries.

¹ THE LANCET, Jan. 25th, 1890, p. 208.

The only law affecting them is the general law on the State inspection of factories and workshops. This law is notoriously inefficient and badly applied. Even when a conviction is obtained the fine imposed is so very small that it

does not deter the culprits.

The Budapest Municipal Bakery was opened on August 23rd last, and after attending the Medical Congress I was able to visit the establishment when it was in working order. It is situated on an open space in the outskirts of the town, surrounded by vacant land which is available to extend the bakery if necessary. The building is lofty and has architectural pretensions. On all sides of the building, the rooms of which are lofty, there is ample space. Instead of the dark cellar bakery we have here a succession of palatial halls. Instead of half-naked men, toiling and sweating as they plunge their arms into the dough, there is magnificent kneading machinery.

Though the journeymen bakers have hardly any occasion to touch the dough or the bread with their hands, the utmost precaution is taken to ensure the most thorough cleanliness. most thorough cleanliness. On entering the factory the workmen are introduced into a large compartment where there is a series of lockers. They are made to undress and place their clothes in these lockers. Then they proceed to a bathroom fitted with hot and cold douches, baths where the bather may lie down at full length, and a plunge bath into which it is possible to take a header and to swim a few strokes. For the operative who has been thus cleansed from head to foot a working suit of clean, washable, special clothes is provided by the municipality. Only when thus bathed and clothed is the journeyman baker allowed to enter the bakery and to work. The walls of the bathroom are of glazed or enamelled bricks, and it is in every respect worthy of a first-class hydropathic establishment. Then as in winter it is too cold to open the windows, fan mechanical ventilators worked by electric power are placed in ventilating shafts to ensure pure air. There is also a medical service. All the workers are medically examined before they are engaged; and while at work they are periodically examined. Thus no one is allowed to touch the bread which the people are to eat unless they are not only perfectly clean but also in thoroughly good health. Further, there is a chemist employed who analyses everything that enters the establishment, even the coal. But there is not much coal used, as oil motors for the dynamos are employed. Needless to say the premises are lighted throughout by electricity.

The flour on arriving at the municipal bakery is delivered by lifts on the third or upper floor of the building. Here the floor is made of solid brick and concreted over so as to keep the mice away. There are large wooden receptacles containing sieves worked by machinery. Into these the sacks of flour are emptied and various kinds of flour mixed. If there is any foreign substance in the flour it is retained by the sieves; then as the flour travels downwards it passes close to a strong magnet which draws away any small particle of metal which may have got mixed with the flour during the process of grinding.² The receptacles are so constructed that they automatically close when 300 kilogrammes of flour have been poured into them. This is the amount which each mechanical kneading machine can treat. There is also a cleaning machine for the flour sacks. The flour extracted from the sacks is used for feeding pigs. When, on a lower floor, the dough has been mixed, fermented, and sufficiently kneaded by machinery, it is shaped into loaves and placed in the patent ovens with little or no manipulation. Throughout there are ample space and light. walls are painted a soft light green, on which the smallest speck of dirt would be seen and from which it could be washed away. There are specially constructed carts to convey the bread to town. These contain two carts to convey the bread to town. These contain two shelves for baskets, each holding 15 two-kilogramme loaves. The sides of the cart are made of canvas, which keeps out the dust, but lets air through. Each loaf has a label that is either triangular, square, or round in shape, according to the quality of the bread; therefore it is not necessary to know how to read in order to tell what sort of bread is being served. These labels bear the arms of the town and certify that the loaf has come from the municipal

The Hungarians, it appears, do not like bread unless it contains a large quantity of potato. They say that if made of pure wheat the bread gets dry in two days, but when potatoes are mixed with the wheat it will keep moist for a long time. There should not, however, be more than 18 per cent. of potato, whereas private bakers often put in as much as 40 per cent. of the cheaper and less nutritious potato. The municipality has had to conform to the general custom of adding potatoes, but takes care that there shall not be more than 18 per cent. of potato in its bread. It sees to it also that the potatoes are sound and clean. They are washed by machinery in a revolving grid. They are peeled by women who are provided with a comfortable dressing-room where they must wash themselves as carefully as they wash the potatoes, and must put on pinafores supplied by the municipality before they are allowed to touch the potatoes. When peeled by these women, the potatoes are cooked by steam and put into a large mill and reduced to pulp.

Thus it will be seen that every care is taken that the bread shall be pure, clean, and nutritious. The whole scheme forms an important step in the direction of what was so often described at the Congress as "social medicine." With the very low rate of wages prevailing in Hungary it does not suffice to have pure and clean bread, it must also be cheap bread, and the municipality does not seek to make any profit on its bread, but only to sell it at a price that will admit of paying the interest on the borrowed capital, and the creating of a sinking fund so that the whole debt shall be cleared off in 50 years. It will then be possible to sell the bread even cheaper, or else to make a profit on it. As it is, the bread was sold at 6 hellers per kilogramme cheaper than the prevailing Thereupon, and within the first week of municipal competition, the private bakers lowered their prices 4 to 6 hellers, or, roughly speaking, about one halfpenny on 2 pounds of bread; a reduction which affects very closely the poorer sections of the large population of Budapest, for whom bread is the chief article of diet. Nor is the municipal competition which has brought about this great economy of the people's money very severe, for the model municipal bakery does not produce more than 25,000 kilogrammes of bread daily. It will get severer unless the private bakeries meet the situation by improving their wares, for the people are most anxious to have bread on which they can rely, which they know is clean, nutritious, and wholesome. The municipality contemplates immediate development of the enterprise, and another loan is being negotiated, this time for 2,000,000 crowns, or £83,333, so as to enlarge the bakery to such an extent that it will be possible to bake daily 200,000 kilogrammes of bread. Then all the hospitals, cooperative societies, charities, and asylums will be able to have the municipal bread.

There remain a few words to say as to the position of the workmen employed. At the Paris municipal bakery they have abolished night work, established the eight hours day and old-age pensions long before these conditions had become planks of the labour platform throughout Europe. At Budapest the conditions are not so good. The workmen employed at the municipal bakery do not get better wages than in the trade generally, but they work shorter hours and under infinitely better conditions, as will be gathered from the description of their hygienic environment. on the premises from 6 A.M. to 6 P.M., but have from 8 to 8.30 for breakfast and from midday to 2 P.M. for dinner, so that it is a nine and a half hours day of actual work. At private bakeries there is only night work. The law on compulsory insurance against accidents and sickness applies, of course, to all the workpeople at the municipal bakeries, so that it is not a great hardship when any of them are kept away through illness. Altogether, and whatever may be the objections raised against municipal trading, all must approve of clean and wholesome bread. No municipality has done so much before to ensure the provision of such bread as that produced at the municipal bakery of Budapest, which was the novelty of novelties shown to the members of the recent International Congress of Medicine.

I do not enter into any arguments about the morality or expediency of municipal trading. My business here is to state the facts.

² I may refer here to a lecture published in The Lancet of August 24th, 1907 (p. 502), by Mr. W. H. Battle on Stricture and Traumatism of the Vermiform Appendix.

DEVONSHIRE CENTENARIAN.—Mrs. Mary Sutherland of Plympton St. Maurice celebrated the 100th anniversary of her birthday on Oct. 19th.

1385

THE SECOND INTERNATIONAL CONGRESS FOR THE REPRESSION OF FRAUD.

(FROM OUR PARIS CORRESPONDENT.)

THE questions on the official programme of this Congress were given in our Paris letter last week. The first day's proceedings were mainly formal, but on the second day some very interesting work was done. In the section for beverages sanction was given: (1) to the blending of wines with one another or with fresh grape juice; (2) to fining; and (3) to the use of carbon for improving damaged white wines. the section for mineral waters it was decided that they should not be kept in casks, that they should not be conveyed from place to place in vessels holding more than 30 litres, and that all the processes which they had undergone ought to be mentioned on the labels. Another section considered that the addition of chicory to coffee ought to be stated, that liquid preparations of coffee ought not to contain chicory, that every resort to methods of colouring coffee as well as the treatment of it with sugar and hygroscopic substances ought to be stated, and that roasted coffee ought not to contain more than 5 per cent. of water. The section for milk and milk products passed a resolution to the effect that any abstraction of cream from milk offered for sale ought to be mentioned on the label for the information of the purchaser, and that butter ought not to contain more than 18 per cent. of water; the artificial colouration of butter was recognised as legitimate, and likewise the addition of antiseptics to butter, if the hygienists sanctioned it. The section for baking passed a resolution to the effect that, inasmuch as official experiments conducted under scientific control had shown the impossibility of giving a loaf an exact weight, the shape of a loaf ought never to be considered as indicating its weight. The section for confectionery decided that when preserved fruit or fruity substances were designated by names which implied preservation with sugar, but were in reality not prepared with fruit and sugar only, the fact should be stated on the label. The section for the provision trade decided that the label "huile des graines" should be compulsory for mixtures of poppy-seed oil, colza oil, and linseed oil with edible oil; that the label "huile fine" should denote a mixture of edible oils; that giving a green colour to vegetables with salts of copper in the proportion of 120 milligrammes per kilogramme was legitimate; and that the name "sardine" should be limited to the alosa sardina.

On the third day the section for beverages considered the question of cider and perry, and defined cider-perry with exclusion of dried apples in cider making; cider" ought to mean cider containing between 2 and 4 per cent. by volume of alcohol; the addition of water or tartaric acid was discountenanced; the only colouring matter which was recognised was caramel. With regard to vinegar, it was decided that dilutions of rectified acetic acid might be called by this name; the addition of organic and mineral products was forbidden, except that (1) alkaline bisulphites in the maximum proportion of 20 grammes per hectolitre, and (2) caramel as a colouring substance were sanctioned; distillery vinegars were excluded. The section for hygiene discussed substances used for colouring. The use of artificial yeast in bread-making was sanctioned, but the making of ornamental designs in sawdust or with "corozo" was forbidden. The use of gelatin in confectionery or preserves was sanctioned, but the addition of alum to substances employed as food was expressly forbidden. On the same day the members of the Congress were invited to a reception at the Hôtel de Ville, where an address of welcome was delivered by the President of the Municipal Council, after whom the Prefect of the Seine and the Prefect of Police said a few words and the President of the White Cross returned thanks.

On the fourth day the definitions which had been proposed for 50 pharmaceutical products by a committee were considered and accepted without important modifications. In the section for hygiene, after a long discussion on the subject of preparing soluble cocoa by roasting the beans with potassium carbonate, it was decided by a large majority (1) that the permissible quantity of potash should be 2 per cent. in excess of the alkalies of the cocoa; and (2) that the resulting product should have an acid reaction. In the evening M. Jean Dupuy, is case by agreement. The student organisations already in existence come under five headings: the University College Women's Union, which admits its members to 17 different clubs and societies; the University College Women's Union, whose members are admitted to the privileges of nine lesser organisations; the University College Women's Union, whose members are admitted to the privileges of nine lesser organisations. The student organisations already in existence come under five headings: the University College Women's Union, whose members are admitted to the privileges of nine lesser organisations. The Bristol Day Training College for Men; the Amalgamated Clubs of the Day Training College for Women; and the University of Bristol Men's Club. The fusion of these into one body, sufficiently united to give it power collectively, and

Minister of Commerce, entertained the organisers of the Congress and the foreign representatives at an official dinner, which was followed by a brilliant reception.

On the fifth day the Congress concluded the consideration of the proposals made and the resolutions adopted by the section for beverages. The definition of vinegar was completed by a clause stating that it was the result of the acetic fermentation either of liquids containing alcohol or of the rectified products of distillation of wood; it was, moreover, resolved that vinegar ought to be sold under a name indicating the source from which it was derived. The Congress then considered the proposals of the section for baking. With regard to flour, the Congress sanctioned as a legitimate proceeding the addition to wheat flour of a maximum of 4 per cent. of ground beans. It also sanctioned as optional proceedings to be notified to the buyer, (1) the mixing of different kinds of cereal flour, the ingredients and their proportions in the mixture to be stated; and (2) artificial bleaching of flour by any recognised inoffensive process. The word bread without any further qualification ought, the Congress considered. to be reserved exclusively for the substance produced by baking dough made with a mixture of wheat flour, yeast (which might be either brewer's yeast or made with dough), potable water, and salt. If the bread was made with another kind of flour it ought to bear the name of the flour (of one or more kinds) which entered into its composi-On the same day M. Bolo, the general delegate for life of the Universal Society of the White Cross of Geneva, gave a luncheon, at which the Under-Secretary of State at the Ministry of War presided, and speeches were made by M. Bolo and others.

On the forenoon of the sixth day a general meeting concluded the examination of the work of the various sections. In confectionery the employment of glycerin and alum would be no longer considered legitimate. The decisions relative to milk and eggs were confirmed. The addition of boron compounds to butter, although in a general way prohibited, was sanctioned for butter to be exported to countries where the addition of borax was allowed, but the addition of nitrate of potassium was prohibited. In the miscellaneous provision trade the definition of larded veal was withdrawn and the permissible proportion of moisture in pork pies was raised from 70 to 75 per cent. Only some unimportant modifications were made with respect to mineral waters.

The official conclusion of the proceedings was announced by Dr. Bordas, speeches being also made on this occasion by various delegates as well as by the President of the White Cross, the organisation responsible for the Congress.

BRISTOL AND THE WESTERN COUNTIES. (FROM OUR OWN CORRESPONDENTS.)

University of Bristol.

A USEFUL little pamphlet has been issued to students and others interested by the Men Lecturers' Committee, summarising the present position of the various athletic and social organisations in connexion with the University, and the possibility of coördinating the whole by means of a "guild of undergraduates." Under the charter provision is made for such a guild. Any definite steps towards its formation are at present held in check by considerations relative to a compulsory subscription. Meanwhile, however, the ground can be surveyed, and the pamphlet already mentioned contains proposed ordinances and regulations. Briefly speaking, these suggest that every University student shall be a member of the guild, that his or her subscription shall be paid at the same time as the registration fees of the University, and that there shall be a central committee empowered to affiliate clubs and societies on such terms as may be determined in each case by agreement. The student organisations already in existence come under five headings: the University College Union, which admits its members to 17 different clubs and societies; the University College Women's Union, whose members are admitted to the privileges of nine lesser organisations; the Union of Social and Athletic Clubs of the Bristol Day Training College for Men; the Amalgamated

also elastic enough to allow liberty to individual clubs and members, is the problem which confronts the University undergraduates.

A School for Mothers.

Bristol is to have a "school for mothers and babies' welcome" on the same lines as the corresponding organisation which has done such good work in St. Pancras, London. An influential ladies' committee has been formed and a beginning made by means of a small exhibition. At this it was shown how sick-room appliances might be improvised by the use of everyday materials, and garments and nursing requisites which could be made at home were also exhibited. The school, which is to start next month, will be worked in connexion with the Broad Plain Settlement in St. Philip's, an east-end district with 65 persons per acre and an infant mortality of 162 per 1000; through the kindness of the warden, Mr. F. N. Colborne, two rooms will be available rent free. A medical lady has been secured to advise the mothers, and help will also be given by several trained nurses and other ladies. It is proposed to charge the mothers ½d. per attendance.

Vaccination in Bristol.

During the year ended Sept. 29th, 1909, the public vaccinators of Bristol performed 3081 vaccinations and 1383 revaccinations, compared with 2721 vaccinations and 53 revaccinations for the corresponding period of the previous 12 months. The increase was due to the small-pox outbreak which occurred in Bristol during the early part of this year.

The South Devon and East Cornwall Hospital, Plymouth.

A strong appeal for increased financial support has been recently issued by the committee of the South Devon and East Cornwall Hospital, Plymouth. The appeal states that the expenditure of the institution is now about £10,000 per annum and that a deficit of £3500 now exists. The committee add that unless the income is larger it will be necessary to close two of the larger wards of the charity.

The Western Eye Infirmary, Exeter.

The annual meeting of the friends of the Western Eye Infirmary was held on Oct. 29th, under the presidency of the Earl of Devon. The medical report stated that for the year ended Sept. 29th, 1909, 3609 patients had been treated; the daily average number of in-patients was 47. The financial statement showed that a favourable balance remained at the end of the year. The committee state that the whole of the amount required for the erection of the new wing was received early in the year, consequently the building was commenced, and it is hoped that it will be completed and formally opened in the early part of 1910.

The Royal United Hospital, Bath.

At the last meeting of the Radstock (Somerset) urban district council it was decided that in future the sum of 5 guineas weekly should be paid by the local authority to the Royal United Hospital, Bath, for any case of diphtheria admitted to that institution by order of the officers of the council in which an operation had to be performed.

Obituary: Charles Reid, M.B., C.M. Edin.

Much regret was felt in Swindon (Wilts) at the death of Dr. Charles Reid, who had been for some years in practice in the town. Dr. Reid, who graduated M.B., C.M. of Edinburgh University in 1888, was 45 years of age at the time of his death. He was formerly a distinguished athlete and Rugby football player; he was captain of the Scottish Rugby team for several years, and possessed about 30 "international caps."

Nov. 2nd.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Association of Public Vaccinators.

THE annual meeting of the Association of Public Vaccinators of England and Wales was held on Oct. 29th, in Liverpool. The retiring President, Dr. Arthur Drury of Halifax presided at the opening, and there were also present members from various parts of the country. The council of the association, in its annual report, emphasised the need for continued and increased efforts in the direction of educating the general public concerning the importance of vaccination as a preventive against small-pox. Mr. J. C. Bradshaw,

public vaccinator of the West Derby Union, was elected President for the ensuing year. At the conclusion of the formal business of the meeting Dr. E. W. Hope, the medical officer of health of Liverpool, read an able paper dealing with some aspects of vaccination and revaccination. Quoting from Dr. Buchan, an authority of a past era, who drew a lamentable picture of small-pox as the dreadful scourge of the country, Dr. Hope contrasted it with present hospital experiences, asserting that though amongst unvaccinated patients small-pox had mitigated none of its severity, amongst those vaccinated the disease was modified according to the efficiency of vaccination. The real sheet-anchor of protection against small-pox was, and must remain, vaccination in infancy, and revaccination at or about the age of 10 or 12 years. A hearty vote of thanks was accorded to Dr. Hope for his valuable paper. The annual dinner of the association was held in the evening at the Adelphi Hotel, Mr. Bradshaw presiding. Amongst the guests were Dr. Hope, Dr. S. Monckton Copeman, Major Ronald Ross, Dr. T. R. Glynn, consulting physician to the Liverpool Royal Infirmary; and Dr. A. Bernard (representing THE LANCET). The toast of "The Association of Public Vaccinators of England and Wales" was proposed by Dr. A. E. Cope and responded to by Dr. Drury, both of whom laid stress upon impressing the public with the importance of vacci-Dr. Drury pointed out that the attack on vaccination by the antivaccinators was nothing short of a veiled attack on the medical profession and science. He also paid a graceful tribute to Mr. John Burns, the President of the Local Government Board, for the fair manner in which he handled the subject of vaccination in the recent Order dealing with the reduction of fees to public vaccinators. In this connexion it may be mentioned that some of the reductions made in fees by boards of guardians in second and succeeding cases of vaccinations and revaccinations performed by public vaccinators in the same house on the same day were opposed to the recommendations of the Local Government Board which suggested that the lowest fee ought not to be less than 2s. 6d. In many unions the guardians reduced the fee to 1s. 6d. "The Guests of the Association," proposed by Mr. Isaac Holmes of Liverpool, was responded to by Dr. Monckton Copeman, Major Ross, and Dr. Glynn. The toast of "Health and Poor-law" was responded to by Dr. Hope and Mr. Harris P. Cleaver, clerk of the West Derby guardians. Several of the speakers paid a high tribute to the efforts of Mr. Charles Greenwood, the organising secretary of the association. The dinner was a most successful gathering, music and singing enlivening the proceedings.

St. Luke's Day Medical Service.

The medical profession of Liverpool and district held their annual service at St. Luke's Church, Liverpool, on Sunday, Oct. 24th (for St. Luke's Day). The preacher on the occasion was the Right Rev. Dr. Diggle (Bishop of Carlisle), who gave an eloquent and instructive sermon. There was a large attendance of members of the profession, who generally wore academic costume. The offertory, as usual, will be devoted to the Medical Benevolent Fund.

Colonial Office Committee on Tropical Diseases.

Amongst the members of the Advisory Committee appointed by the Colonial Secretary on the subject of tropical diseases is the name of Sir Rubert Boyce, F.R.S., of the University of Liverpool.

North of England Association of Dublin University Graduates:
Annual Dinner.

The members of the North of England Association of Dublin University Graduates held their annual dinner at the Adelphi Hotel on Monday evening, Oct. 18th, Sir Robert Ball, F.R.S., presiding. The principal speakers were Sir Robert Ball, Professor Mahaffy, M.V.O., Mr. Edgar Browne, Archdeacon Madden, and the Lord Mayor of Liverpool The dinner was largely attended, covers being laid for 120 gentlemen. The success of the gathering was largely due to the efforts of the honorary secretaries, Dr. F. J. S. Heaney and the Rev. H. D. Morgan.

The Liverpuol School of Tropical Medicine: Banquet to Sir Alfred Junes, K.C.M.G.

The students and staff of the School of Tropical Medicine entertained Sir Alfred Jones (the chairman of the school) to dinner at the Exchange Station Hotel on Nov. 1st. The chair was occupied by Mr. A. McCabe-Dallas (India), senior

student of the school. Letters of apology for absence were received from Lord Milner, who enclosed a contribution to the funds of the school, Colonel Seely, M.P., and Sir Edward Evans. Special interest was associated with the function from the fact that it represented a kind of leave-taking of Dr. J. W. W. Stephens, who is about to depart for special research work in Egypt; of Dr. H. Wolferstan Thomas, who is proceeding to the Amazon on a yellow fever expedition; and of Dr. Anton Breinl, who is going to Queensland as the director of the new school of tropical medicine there. Prior to the toast-list Sir Alfred Jones, on behalf of the school, presented Dr. Breinl with a dressing-case, silver cigarette-case, and an address-book. In making the presentation Sir Alfred Jones said that the recipient had greatly distinguished himself, and had added to the reputation of the school. The toast of "The Staff and Students of the School" was replied to by Major Ross, who said that he hoped the work of research would not be stopped for lack of funds, as great developments were coming on in connexion with the fight against malarial diseases. Other speeches followed.

Nov. 2nd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

General Council of the University of Edinburgh.

THE statutory half-yearly meeting of the General Council of the University of Edinburgh was held on Oct. 29th, Principal Sir William Turner, K.C.B., occupying the chair. Various matters of medical interest were dealt with; the first of these bore upon the preliminary examination, a motion being carried to the effect that it be represented to the University Court that it was desirable to reconsider the arrangements under which the preliminary examinations in medicine, arts, and science were conducted. It was also agreed that it be represented to the University Court that the rearrangement of the bursary examinations under the powers contained in the recent ordinance should be carried through without delay. Dr. Norman Walker then proposed the following motion, of which notice had been given :-

To remit to the Business Committee to consider and report as to the desirability of procuring by an amending ordinance of the University Court or otherwise further improvements in the medical curriculum and examinations.

This motion was based upon the report which was the outcome of the labours of a committee of the Pathological Club-The main points were that medical study should begin in the summer session, and that if a fixed curriculum were insisted on many of the difficulties which arise in arranging for the later subjects would disappear. While it was recognised that the University was liberal in recognising courses of study in other universities as qualifying for entrance for the earlier professional examinations, it was regarded as advantageous to the University to insist that the later subjects of the medical course should be studied in Edinburgh. tion was also drawn to the tendency for each subject in the medical course to be treated as if it were a water-tight compartment, and that this might be avoided by consultation and cooperation between different departments. Dr. James Ritchie seconded the motion. Professor H. Harvey Little-john, dean of the Faculty of Medicine, said that they were fully aware of the many difficulties in the way of medical education and the order of the curriculum, and they would welcome suggestions from the Business Committee of the

The Parliamentary Representation of the University of Ėdinburgh.

Sir John Batty Tuke, M.P., who has represented the Universities of Edinburgh and St. Andrews for a number of years, has intimated that he is not again to seek re-election. Simultaneously it is announced that Sir Robert Finlay has been selected by the Unionist party as the champion of their cause at the next election. Sir Robert Finlay is an Edinburgh man, and became a graduate in medicine before he entered the legal profession. He represented the Inverness Burghs for a number of years before he lost his seat at the last General Election. He has been Lord Rector of the University and was a well-known member of Mr. Balfour's Government. It has not yet been disclosed whether he is to be opposed or not. Sir John Batty Tuke was opposed at the last election by Mr. St. Loe Strachey.

Edinburgh Royal Infirmary.

The managers of the Edinburgh Royal Infirmary have approved the following minute regarding Professor J. Chiene:

Owing to his resignation of the chair of surgery, which he has so long adorned, the managers have had regretfully to part with the services of Professor John Chiene, and Professor Chiene's connexion with the Royal Infirmary has been a long and brilliant one. He received the appointment of assistant surgeon in 1871 and was promoted to the post of acting surgeon in 1878. Four years later he became professor of surgery in the University of Edinburgh and was entrusted by the managers with charge of the wards attached to that chair. His services, given wholeheartedly and enthusiastically, have thus extended continuously over the long period of thirty-eight years. The managers desire, in now taking leave of Professor Chiene in his capacity of one of the surgical staff of the Royal Infirmary, to record the very high esteem in which they hold him as a man, a surgeon, and a teacher, and their grateful recognition of the unfalling kindness which has throughout characterised his relations with his colleagues and the skill and interest he has shown in his care of the many patients who have passed through his hands. His skilful and judicious treatment of patients from far and near and his good influence over them and all with whom he has worked in the infirmary will be long and gratefully remembered. Owing to his resignation of the chair of surgery, which he has so long remembered.

The minute ends by good wishes for his health and appointing him a consulting surgeon to the institution.

The Edinburgh Medico-Chirurgical Society.

The billet for the first meeting of the session 1909-10 has just been circulated. It is pleasing to see that Dr. Byrom Bramwell has been nominated for the presidential chair in succession to Dr. James Ritchie, for no one has been a more faithful contributor to the proceedings of the society in past years than he.

Pulmonary Tuberculosis in Glasgow.

The health committee of the Glasgow corporation has at a recent meeting adopted the following recommendations put forward in the memorandum prepared by Dr. A. K. Chalmers, the medical officer of health:

- 1. That the corporation, as local authority, resolve that the Infectious Disease (Notification) Act, 1829, shall, for a period of three years, apply to pulmonary phthisis.

 2. That, in addition to the tuberculosis dispensary at present conducted in the Sanitary Chambers, similar dispensaries be provided in the eastern, western, and southern districts of the city.

 3. That a nurse be appointed to each dispensary for systematic visitation of the homes and families of those in attendance thereon.

 4. That the work of home visitation be placed under the charge of a medical assistant appointed for the purpose.

First Annual Report of Inverness Sanatorium.

The first annual report of Inverness Sanatorium states that though the committee is aware that the institution has existed too short a time to enable it to speak very definitely as to the results, it feels entitled to state that a good beginning has been made. The general tone and discipline of the sanatorium have been excellent, and the committee expresses its consciousness of the services rendered during the first year by Miss Sturgess, the matron. Dr. John Macdonald, medical officer of health of Inverness-shire, reports that between November, 1907, and November, 1908, 42 patients were admitted. The total percentage in which the disease was arrested was 28.5 and improvement 47.2, giving a percentage of benefit in 75 7 cases. The receipts on building accounts amount to £3355 and there was a balance in hand of £309. The proceeds of the Beaufort bazaar, amounting to £2987, have been invested in the debenture stock of railways—£1000 at 3½ per cent. and the balance at 4 per cent.

Nov. 2nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal Co lege of Physicians of Ireland.

AT the annual meeting of the Royal College of Physicians of Ireland the following officers were elected for the coming year:—President: Dr. Andrew J. Horne. Vice-President: Dr. E. MacDowel Cosgrave. Censors: Dr. MacDowel Cosgrave, Dr. E. Hastings Tweedy, Dr. J. B. Coleman, C.M.G., and Sir W. J. Thompson. Representative on the General Medical Council: Sir John W. Moore. Representatives on the Committee of Management: Dr. Walter G. Smith, Sir John Moore, and Dr. James Craig. Treasurer: Dr. H. T. Bewley. Registrar: Dr. Craig. Librarian: Mr. R. G. J. Phelps. Dr. Walter G. Smith was elected King's Professor Phelps. of Materia Medica and Pharmacy in the School of Physic.

Ireland, and Dr. Henry Jellett, King's Professor of Midwifery in the same school.

Royal Academy of Medicine in Ircland.

At the annual general meeting of the Royal Academy of Medicine in Ireland, held in the Royal College of Surgeons on Oct. 8th, the following resolutions were adopted in

That the President and Fellows of the Royal Academy of Medicine in Ireland assembled at this the first annual general meeting held sine the lamented death of Professor Alec Fraser desire to place on record their sense of the great loss which the Academy has thereby sustained. The late Professor Fraser was President of the Section of Anatomy and Physiology during the sessions 1893-4 and 1894-5. He made his first important communication to the Academy in January, 1890, on "Operations on the Brain," and from that date until his death he was a constant contributor to the Section of Anatomy and Physiology. The President and Fellows take this opportunity of offering to Mrs. Fraser an expression of sincere sympathy with her in her bereavement.

That the Fellows of the Royal Academy of Medici e in Ireland at this their annual meeting do hereby convey to Mrs. Cunningham an expression of their respectful and sincere sympathy with her and the several members of her family on the occasion of the death of Professor Daniel John Cunningham, F.R.S., formerly a distinguished Fellow of the Academy, and one of the most ardent supporters of the Section of Anatomy and Physiology.

The meeting adopted a new rule to the effect that registered

The meeting adopted a new rule to the effect that registered medical practitioners temporarily resident in Dublin may be elected Associates of the Academy for the period of one

Apotheoaries' Hall: Inauguration of a New "Medical and Soientifio Society.

The inaugural meeting of the Medical and Scientific Society of the Apothecaries' Hall was held on the evening of Oct. 28th, when many leading members of the medical pro-fession accepted the invitation to attend. The progressive aims of the society were shown alike in the choice of lecturer to deliver the opening address (Professor Mettam, Principal of the Royal College of Veterinary Surgeons, Ireland) and the subject on which the lecturer spoke-viz., "Diseases of Animal Communicable to Man." The sections of the theme specially dealt with were tuberculosis, glanders, rabies, anthrax, foot and mouth disease, vaccinia, and actinomycosis. Psittacosis was also referred to, and the microscopic manifestations and general history of ringworm and trichinosis. In discussing tuberculosis Professor Mettam dwelt on the variable degrees of infecting power and virulence displayed by different tubercle bacilli, and stated that he doubted the possibility of distinguishing a human type and a bovine type, adding the important statement that "it appears that the more virulent an organism is the greater the probability that it comes from a bovine source." He expressed his belief, too, that the tuberculosis of birds (the common fowl, pheasant, turkey, and so on) will in a time not remote be recognised as the result of a cause which is "only a variety of a common stock."

Officers of Health, Medical and Veterinary.

The October meeting of the Council of the Irish Medical Association brought into strong relief some of the difficulties and incongruities connected with the administration of sanitary and hygienic law in Ireland and the anomalous position of the medical officers of health, each of whom is in charge of, and entirely responsible for, the sanitary condition of his district. For an annual donation of £15 all insanitary dwellings, adulterated food, and defective drains, as well as all other visible and tangible items which are believed—or are defined by law—to be injurious to public health, must be inspected and reported on; all cases of infectious diseases, in the districts subject to the provisions of the Notification Act, must be notified by that responsible officer, who must also see to the removal of the patient who is the subject of infection, and take care that proper disinfection of the premises follows. His time is necessarily seriously encroached on by these public duties, to which all conditions and exigencies of private practice must yield, and recent legislation has all tended to increase the weight of this professional burden, while it subjects him still further to friction with boards of guardians and district councils, and to private—and very positive—ill-will in such cases as the necessarily numerous ones of suspected incipient tuberculosis. It also, in the form of the Dairies and Cowsheds Order, obliges him to inspect and report on the sanitary conditions of the dairies, cowsheds, and milkshops, a duty which necessarily includes inspection of the dairy cows and their byres. A recent step has been taken by our Irish

legislators which brings into greater prominence the unfairness of all legal provision in every matter connected In order to make the bovine with medical finance. sanitation still more secure a veterinary inspector has been appointed in certain districts for the purpose of looking after the sanitary conditions of the cattle. His duties in this department cannot be said to clash with those of his routine professional work; they rather tend to increase his professional practice than to retard the performance of its duties; and they are less than likely to lead to the frictional attitude of public bodies which the medical officer is so prone to encounter. Yet a recent veterinary appointment of this class is dowered with £75 per annum five times the amount paid to the medical inspector for the carrying out of duties often decidedly incongruous with his normal professional ones, while still oftener damaging to the efficient attention required in his daily medical practice and his popularity as a medical visitant and adviser. Surely this is a state of things which calls for concerted action on the part of medical men and for the modifying legislation which should be made to follow.

The Royal University of Ireland.

The last degree day of the Royal University, which terminated its existence on Oct. 31st, took place on Oct. 29th, and surpassed any former occasion for extreme rowdiness. Certain of the students took complete possession of the great hall in which the ceremony took place, and from one of the galleries they suspended a white flag, bearing in black letters R.U.I., surmounted with a representation of a skull and crossbones, and underneath R.I.P. They flung squibs and bags of flour and rice among the audience, rendering the situation one of great discomfort, and, indeed, of imminent peril, for the company. The Vice-Chancellor, Sir Christopher Nixon, occupied the chair, but not one word of his speech was heard owing to the yelling, and while he was endeavouring to get a hearing a strip of calico was drawn across the centre of the hall having on it inscribed "Irish Compulsory" (referring to the demands of the Gaelic League and the Sein Feiners). The Senate conferred honorary degrees on all those of its own members who had not had already received such decorations. The number was actually 19, of whom 16 were graduates of some university, and of those honoured in this way the following are members of the medical profession: - Degree of LL.D.: Sir Francis Cruise, Dr. John Walton Browne, Dr. Richard Whytock Leslie, Dr. John Campbell, and Dr. W. R. Huggard; degree of D.Sc.: Professor Alexander Macalister. Towards the close of the proceedings a sensation was caused by the introduction of a hydrant by which a copious torrent of water was turned on. Then parts of the hose-pipe were cut and someone sent a piece whirling through the air towards the platform where the Senate was seated. After the termination of the proceedings the students congregated outside the University buildings, and threw rice and squibs at the police who, however, prevented them from re-entering the building and finally scattered them. Thus passeth the Royal University after a life of 30 years. The old Queen's University also lasted about 30 years. Absit omen!

Insanitary Areas in Belfast.

A scheme for dealing with insanitary areas in Belfast is under consideration. It will deal both with insanitary houses and areas, and will provide air spaces through the city, will widen streets, and will get rid of culs-de-sac. It was also proposed to do away with double-tenancy houses, in which people were living in very unsatisfactory hygienic conditions. The city surveyor and a committee are at present working on the matter. The medical report, presented at the monthly meeting of the city council on Nov. 1st, showed that between Sept. 19th and Oct. 23rd the death-rate from all causes was 13.9 per 1000, from chest affections 3.6, and 1.9 from zymotic diseases. The cases of infectious diseases notified were 123, as against 82 in the preceding month, the increase being in typhoid fever, scarlet fever, simple continued fever (really typhoid), and puerperal fever. The increase in typhoid fever, being 62.50 per cent., is the most serious, and of the 16 cases notified 5 were ascertained to be directly attributable to milk supplied from a dairy outside the city boundary; and the medical officer of health reports that it is very probable that some of the other cases may have been indirectly due to milk imported into the city.

Nov. 2nd.

PARIS. (FROM OUR OWN CORRESPONDENT.)

Rapid Radiography.

AT a meeting of the Paris Société de Médecine held on Oct. 8th M. Desternes showed a series of radiographic pictures taken with an exposure of less than 30 seconds. The advantages of the new process are a diminution of the fatigue and discomfort experienced by the patient, as well as greater steadiness of the region examined. For these reasons the pictures not only gain in sharpness and precision but views of regions affected by the respiratory movements can now be obtained of a more satisfactory description than has hitherto been possible.

Treatment Before and After Abdominal Operations.

At the twenty-second French Congress of Surgery held in Paris from Oct. 4th to 9th several communications were received relative to the treatment preceding and following operations on the abdomen. M. Pozzi, recognising that dis-infection by means of hot air was not practicable for all surgeons since it required expensive apparatus, said that he accomplished this kind of disinfection by scraping with a sharp spoon followed by the actual cautery, but not by the thermo-cautery. M. Princeteau, speaking especially of abdominal surgery in the child, said that he was opposed to purgation before an operation, as it might have an injurious effect on the mucous membrane. M. Chavannaz having compared the advantages and the disadvantages arising when females upon whom laparotomy had been performed left their beds at an early stage, expressed himself as unfavourable to the practice. M. Delangre and M. Lenormant said that they had met with three cases of acute duodenal occlusion after operations, the cause probably being gastric lavage and the position in which the patient lay. M. Bérard and M. Walther called attention to the advantage of disinfecting the skin by tincture of iodine. M. Pauchet urged on the congress the necessity of hospital treatment for all cases of operation, the ntility of vegetarian diet, the advantages of non-fermentable food, the importance of attention to the state of the mouth, and the good effects of systematic respiratory exercise. M. Paul Delbet insisted on the advantages of performing operations in a special institution rather than in the patients' own homes. M. Sorel said that in his opinion the progress of surgery was in inverse proportion to the amount of manipulations and apparatus and to the number of assistants; he was also in favour of using tincture of iodine as a disinfectant. M. Cazin and M. de Fourmestraux said that patients ought not to leave their beds at an early stage.

Treatment of Detachment of the Soalp.

M. Pierre Delbet has had under his care two females suffering from detachment of the scalp, in whom cicatrisation of the extensive wound had not taken place after a year and serious complications had ensued. In an account of these cases which he gave at a meeting of the Academy of Medicine on Oct. 12th he said that this injury when sustained during industrial employment was almost confined to females whose long hair was caught in a carding machine or something of a similar description. The scalp was then stripped from the skull along a line drawn on a level with the eyebrows and the external ear, passing below the external occipital protuberance. The injury was not extremely painful. As the extensive denudation could only be repaired by skin-grafting on Thiersch's principle, M. Delbet adopted this method and the grafts adhered, although many of them were implanted directly on the diploe. To be successful these grafts must be broad and must overlap at the edges. With these two patients the cicatrisation obtained by M. Delbet in this way was quite substantial, the period elapsed since the completion of repair having been 16 months in one case and two years in the other.

Albumin in Tuberculous Sputum.

At a meeting of the Société Médicale des Hôpitaux, held on Oct. 15th, M. Roger said that examination of the sputum for albumin was as simple, easy, and important as examination of the urine for albumin. The sputum was rubbed up with water, some drops of acetic acid were added, the whole was thrown on a filter, and the ordinary tests for albumin

were applied to the filtrate. If heat was employed it was necessary to add a little common salt, as without this precaution the albumin did not coagulate. Observations to the number of 151, collected with the assistance of M. Lévy-Valensi, made it extremely probable that the sputum of tuberculous patients always contained albumin. When there was no reaction for albumin tuberculosis was, as a rule, not present, and although the converse might not be true the practical importance of the symptom was evident.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

Operative Results of Nephrectomy.

Dr. H. Wildbolz, lecturer (privat-docent) at the University of Berne on diseases of the urinary tract, has just published his results of a series of 100 nephrectomies performed by him during the last eight years. Nephrectomy used to be considered a most dangerous operation. In 1891 Professor Albert of Vienna wrote in his well-known text-book on kidney merely as an operation to avoid. Yet one finds surgeons ready to undertake it." The statistics of Gross in 1885 gave 44.6 per cent. of fatal cases; this justifies Professor Albert's opinion. In 1902 Kuster described a mortality of only 25 per cent. in 1521 cases operated on. Out of 100 cases Dr. Wildbolz only lost four, 90 of these operations being performed for tuberculous kidney. The favourable result was greatly due to the fact that medical practitioners sent him the patients in early stages of this dire disease. One patient died from myocarditis; another from uramia owing to extensive degeneration of the other kidney; the third case suddenly died from a clot in the pulmonary artery which was detached from a thrombosed renal vein on the tenth day after a successful operation; the fourth died from paralytic ileus. Ether narcosis was generally employed. The exact examination of the bladder and especially of the secretion of each kidney separately, when possible, is of the most vital diagnostic, prognostic, and therapeutic importance.

Mortality from Certain Infective Diseases in Switzerland.

The Swiss Federal Statistic Department has issued a report on mortality from whooping-cough, measles, scarlet fever, and diphtheria in children under 15 years of age. The mortality is decreasing from year to year. From 38 4 per 10,000 from 1876 to 1880 it has receded to 20 per 10,000 from 1901-05. A further reduction to 18·3 and 16·7 per 10,000 has ensued in 1906 and 1907.

Treatment of Epilepsy by Reduction of Chloride of Sodium in the Dietary.

Dr. A. Ulrich, senior physician to the Epileptic Home in Zürich, has continued with satisfactory results his treatment of epilepsy by reduction of salt in the dietary.\(^1\) Even in obstinate and very chronic cases the epileptic attacks diminished by one-half, in some cases by 79, 82, and even 97 per cent. The patients all felt better in themselves. Dr. Ulrich has now decided to make use of this dietary for the majority of his 213 patients. Dr. Hans von Wyss's experiments on the action of bromide salts on the human organism go to prove that they act through elimination of the chloride of sodium. Dr. Ulrich's further experiments prove that an increase of chloride in the dietary is often followed by an increase of epileptic attacks. This explains the rationale of this dietetic treatment.

Zürich, Nov. 1st.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Unveiling of a Statue of Professor Albert.

In memory of the famous surgeon, Professor Albert, who from 1881 till 1900 was the director of the first surgical clinic of the Vienna General Hospital, a statue was a few days ago unveiled in the Aula (or hall of honour) of the University of Vienna. Contributions from his numerous pupils, friends, and grateful patients enabled the committee to

¹ See The Lancer, Sept. 12th, 1908, p. 846.

have a life-sized monument erected, showing Professor Albert during an operation demonstrating to students a new fact. The ceremony was attended by a large number of personal friends, and of course the official representatives of medical bodies were present as well. Professor Hochenegg, one of Professor Albert's earliest and most prominent pupils, now himself director of the surgical clinic, delivered the principal address, in which he enumerated the numerous merits of his former master. A short history of his life was also received with great interest. Professor Albert was the first surgeon to make a transplantation and substitution of nerve on the living human body; his methods of arthrodesis and of suturing tendons are now generally used. He was also the first in Austria to use Lister's method of antisepsis which he learned from Lister himself in England. The students were greatly impressed by his convincing and instructive method of teaching. It was his custom to introduce clinical methods of instruction at an early stage of the curriculum and he used to say that a general practitioner in a country place must know enough surgery to be his own consultant. A touching expression of the esteem in which he was held by his friends consisted in a wreath bearing the words: "Magno medico, maximo magistro, grato animo," which was deposited at the feet of the statue.

Public Appointments and Private Practice.

The municipal board of health has recently invited applications for several medical appointments in a new "central Kinderheim" (a central orphan asylum) to be built in a short time, but with the clear understanding that the positions in question would occupy the entire time of the incumbent, so that he could not engage in private practice. This is an almost new departure in Austria, as at present there are extremely few-hardly more than two or three-medical institutions in the whole country conducted on this principle. The only drawback is that the board has not stated what salary would be paid to these officers. As it is well known that the remuneration for public appointments is not sufficient, at least on its present scale, to satisfy a medical man of good qualifications, it must be assumed that the sum would be at least 10,000 kronen (about £400) a year. Much comment has been aroused by this innovation on the part of the hitherto not very pro-medical municipality of Vienna. Medical circles are unanimous in their approval because it generally happens that appointments of this nature are only sought after for the purpose of obtaining a title such as Primararzt or Director, which enables its holder to charge higher fees, since the public are so partial to medical men who possess distinctive appellations of this kind. The holders of appointments, therefore, interfere seriously with the earning possibilities of the men who have not been lucky enough to obtain one of the ill-paid permanent appointments. On the other hand, amongst the general public it is considered as only fair that an appointment should secure the entire services of a competent man. If this becomes the rule satisfaction would be general.

Dissatisfaction amongst Medical Students.

Several grievances of a general nature have recently caused some irritation amongst the students of medicine both of the preliminary and the advanced years of the curriculum. By decree of the Senate, every student must now pay a small sum, amounting to a few shillings per year, for the use of the library of the University. Even more unpopular, however, was a charge of 10 kronen (about &).
made for the so-called gynæcological "internate," or term of practical instruction at the bedside, which was intro-duced this winter term. This latter charge was made for only a fortnight's accommodation in the hospital and was felt to be an unnecessary burden. Meetings were held and resolutions were forwarded to the Dean of the Faculty asking that at least the last-mentioned payment might be discontinued. The attitude of the students was so unanimous, and the policy of the managing board was so judicious, that the charge was done away with. A much more important incident, and one more illustrative of the narrow views held by some bureaucratic individuals, has occurred in connexion with the Institute for Physical Teaching. This institute is capable of holding about 120 students and was too small for its purpose even 20 years ago. Petitions for the erection of a new building have been made yearly for a long time and have been as constantly

the institute, and Professor Lecher, who lectures on Physical Principles, had to ask them to abstain from coming to the classes as their presence involved a danger in case of fire, and certainly was detrimental to their own health on account of the overcrowding. The students responded to his request, but demanded a suspension of lectures, so that either all or none might have the benefit of his teaching. Professor Lecher readily complied with their wish, and made the fact known to the Ministry of Education that instruction in this important branch of general education was made impossible by lack of proper teaching accommodation. He added that the students would continue to strike unless they had a definite promise that things would be reformed in a radical way within a reasonable time. Up to now, however, he has not received any satisfactory reply, so the students declared at a repetition of the attempt to hold the class that they would render all such teaching impossible by a "noisy strike." In certain instances this is the only way here of convincing the superior authorities that matters are not going well.

Nov. 1st.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

The Prevalence of Plague.

THE plague returns for the week ending Sept. 25th show the following deaths. Bombay Presidency reported 938, Madras 155, Bengal 43, the United Provinces 418, the Punjab 181, Burma 18, the Central Provinces 963, Mysore 243, Rajputana 402, and Central India 219. The mortality in the Central Provinces is mainly in Nagpur city, where 656 deaths occurred during the week.

The Health of Bengal.

Indian sanitation is generally somewhat primitive, and even the most advanced places are behind the times according to Western ideas. But it seems to be a fact in Bengal, at any rate, that though progress in urban sanitation is slow it is quite perceptible. Excluding the mortality from plague, the figures for the last seven years show that the public health in the towns has always been better than in the rural areas, and the difference in favour of the urban death-rate has been increasingly marked during the last four years. The year 1908 was unhealthy, especially in the early months, the cholera mortality, 268,908, being the highest on record. On the other hand, to the destruction of mosquito larvæ during the abnormally dry months preceding the monsoon is ascribed the decreased severity of fever. At the same time the Sanitary Commissioner does not appear to hold to the mosquito theory in its entirety. The districts most affected with "fever" can none of them be described as water-logged, and the Sanitary Commissioner apprehends that "the deficiency in the rainfall necessary to scour away the accumulated surface impurities affected pre-judicially the health of these tracts," which is another way of saying that the prevalence of fever can be attributed to other causes than the anopheles mosquito. Plague was much less prevalent than in previous years, but it is reported that popular prejudice against scientific preventive measures is as stubborn as ever. Evacuation of infected dwellings is practically the only preventive measure at all in favour. Rat destruction was carried on by organised gangs in most of the districts of Behar, though the use of poison for this purpose was objected to by the people, particularly in Shahabad. The expenditure by municipalities upon sanitary improvements increases slowly, but it is far below what it should be, and there is a tendency, sternly deprecated by the Lieutenant-Governor, to look to Government for substantial grants for sanitary projects. problem is generally one of funds, and until more ample means are available the progress of sanitation in Indian towns must necessarily be slow.

Malarial Fevers in Bengal.

occurred in connexion with the Institute for Physical Teaching. This institute is capable of holding about 120 students and was too small for its purpose even 20 years ago. Petitions for the erection of a new building have been made yearly for a long time and have been as constantly refused. There are now over 400 students attending making up of quinine in small packets for sale among the

people has now been concentrated in the jail for juveniles at Alipore, and 30 boys are employed in this work. In order to make the use of the drug more popular among the public in malarial districts it is being put up in tablet form. The necessary machinery has been procured and the manufacture of the tablets is proceeding. Special arrangements have been made to stock these in large quantities, as well as 10-grain pice-packets; and the Inspector-General of Prisons is confident of being able to meet any sudden demand when malaria appears in epidemic form. Over 4,000,000 picepackets were made up and despatched to various post-offices during the past year, and operations henceforward will be on a still larger scale.

Ambulance Work in India.

It would be satisfactory to hear that a generous response was being made to the appeal for further support in behalf of the St. John Ambulance Association in Bombay. The association has long carried on a quiet but useful work in the town and its apparatus and skilled ambulance parties have been freely placed at the disposal of the general public on occasions when there is a more than ordinary chance of accidents occurring. Four ambulances are now kept for general use, including two new wheeled ambulances at the head police office and Colaba police station respectively, the former having attached to it a trained squad of attendants. It is obvious that this service cannot be considered adequate for a city of the size of Bombay, and the association is endeavouring to place its work on a broader It deserves a little cooperation both from the municipality, to whom it is appealing for funds, and from the public whose assistance it invites both by personal service in the trained corps and by subscriptions.

A centre of the St. John Ambulance Association for the Southern Punjab has just started work at Kasauli. It has been organised by Lieutenant-Colonel O. R. A. Julian, C.M.G., who is a specialist on ambulance matters, as he has acted as adjutant of the Royal Army Medical Corps Training School at Aldershot. The committee of the new centre is under the presidency of Major-General J. D. Pilcher, C.B., commanding the Sirhind Brigade. The vice-presidents are Colonel A. M. Crofts, C.I.E., P.M.O., Sirhind Brigade; Mr. R. Sykes, Deputy Commissioner; and Colonel H. Grey, C.S.I. The chairman is the Rev. A. H. Hildesley, M.A., principal of the Lawrence Military Asylum, who has long taken an interest in the work of the association, and has organised numerous ambulance classes for the boys under his control. Colonel D. Semple, R.A.M.C., the director of the Central Research Institute, is the vice-chairman, and the members include the Commandant of Kasauli and the Cantonment magistrates of Kasauli and Ambala and many influential officers and civilians. Lieutenant-Colonel Julian acts as honorary secretary himself. With such a strong committee and energetic and experienced secretary there can be little doubt that the centre has a long career of usefulness before it. Sept. 30th.

Medical News.

University of Cambridge.—The following appointments have been made: - Professor of Zoology and Comparative Anatomy: J. S. Gardiner, M.A., Caius College. Quick Professor of Biology: G. H. F. Nuttall, Sc.D., reelected for three years. Demonstrator of Experimental Psychology: E. O. Lewis, B.A., St. John's College.—The following degrees were conferred on Oct. 28th :-

M.D.-G. Cowan, King's; H.J. D. Birkett, Trinity; and H. L. Dixon, Non-collegiate.

M.B.—E. G. Wheat, Christ's.

B.C.—R. W. S. Walker, Trinity.

The following examiners have been appointed: -First M.B.: C. T. R. Wilson, in physics; J. S. Gardiner, in biology; and R. H. Adie, in chemistry. Second M.B.: Dr. Duckworth and Mr. Addison, in anatomy; Dr. Anderson and Professor Halliburton, in physiology. Third M.B., Part I., C. R. Marshall and W. E. Dixon, in pharmacology; Professor Woodhead and Dr. Leith, in pathology.

FOREIGN UNIVERSITY INTELLIGENCE. Amsterdam: Dr. J. J. Houwink has been appointed Professor of Dermatology.—Breslau: Dr. Bruno Heymann, privatdocent of Hygiene, has been granted the title of Professor .-

-Freiburg: Dr. Hurenknecht, privat-docent of Odontology, has been granted the title of Extraordinary Professor. Gratz: Dr. Robert Hesse has been recognised as privatdocent of Ophthalmology.—Halle: Dr. Alexander Stieda, privat-docent of Surgery, has been granted the title of Professor.—Kharkoff: Dr. Krimberg of Moscow has been appointed Extraordinary Professor of Medical Chemistry.—Kiel: Dr. Franz, Professor of Midwifery and Gynæcology in the University of Jena, has been offered the chair of the late Professor Pfannenstiel. - Leyden: Dr. J. Boeke has been appointed Professor of Anatomy in succession to Dr. Langelaan, resigned.—Moscow: Dr. N. S. Kishkin, Extraordinary Professor of Medical Diagnosis, has been promoted to an Ordinary Professorship. - Naples: Dr. Pietro Michele Barberis and Dr. Luciano Rossi have been recognised as privat-docenten of Medical Chemistry.—Prague (German University):
Dr. Alexander Scheib has been recognised as privat-docent of Midwifery and Gynæcology, Dr. Leopold Moll as privatdocent of Children's Diseases, and Dr. Eduard Weil as privatdocent of Hygiene.—Sienna: Dr. Cesare Maroco of Rome has been recognised as privat-docent of Midwifery and Gynæcology.

ROYAL INSTITUTION. — The eighty-fourth Christmas Course of Juvenile Lectures, founded at the Royal Institution in 1826 by Michael Faraday, will be delivered this year by Mr. William Duddell, F.R.S., his subject being "Modern Electricity." The course, which will be experimentally illustrated, commences on Tuesday, Dec. 28th, at 3 o'clock, and will be continued on Dec. 30th, 1909, and Jan. 1st, 4th, 6th, and 8th, 1910.

GLASGOW UNIVERSITY CLUB (MANCHESTER AND DISTRICT). -The annual meeting of the club, followed by the fourth annual dinner, will be held at the Queen's Hotel, Manchester, on Tuesday, Nov. 16th, at 6 P.M. prompt. Sir Henry Craik, M.P., Sir Hector Cameron, and Dr. G. S. Middleton have signified their intention to be present. The honorary secretary of the club is Dr. D. Richmond, 176, Drake-street. Rochdale, to whom notice should be sent by those who wish to attend the dinner.

Health of the Post Office Staff.—The Postmaster-General (the Right Hon. Sydney Buxton, M.P.), in his report for the year ended March 31st, 1909, just presented to Parliament, states that the health of the staff during the year was, on the whole, satisfactory. There was a recurrence of influenza during certain periods of the year, and 23 deaths and three retirements were directly attributable to this cause. 58 deaths and 111 retirements were due to diseases of tuberculous origin. Inquiries were instituted into the nature and prevalence of the disorder known as "telegraphists' cramp," a nervous affection to which telegraphists using the Morse telegraph key are liable. result of the inquiries was not altogether conclusive, as difficulty was experienced in many cases in distinguishing between telegraphists' cramp and other affections which interfere with an operator's power of manipulation. It has been ordered that telegraphists' cramp be added to the Third Schedule of the Workmen's Compensatian Act as a disease in respect of which compensation should be payable, and that, so far as Post Office servants are concerned, the medical officers of the Post Office shall be substituted for the certified surgeons appointed under the Factory and Workshop Act, 1901, as the persons by whom in the first instance the presence of the disease should be certified. As a result of representations made by the Postmen's Federation the Postmaster-General deputed Dr. J. Sinclair, second medical officer to the Post Office, to conduct an inquiry jointly with Mr. D'Arcy Power, nominated by the Federation, into the physical effect of stair-climbing and cycling upon postmen. As regards stair-climbing, the result of the inquiry was to show that the physical strain produced was not of an abnormal character and was not productive of injury to health. Steps have, however, been taken to obtain permission for postmen to make use of the lifts in large blocks of flats, and the amount of stairclimbing has thereby been reduced to a minimum. As regards cycling duties, Dr. Sinclair and Mr. Power made a number of recommendations, most of which have already been carried out. Definite limitations have been imposed on the weight to be carried on a bicycle or tricycle, the daily distance to be traversed and the rate of speed to be maintained, and a searching medical examination has been instituted in order to

prevent unsuitable persons from being employed on cycling duty. Various minor regulations have also been laid down. The Postmaster-General adds: "I feel greatly indebted to the two medical gentlemen in question for having enabled me to place these arduous portions of a postman's daily duty on a satisfactory footing."

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—
The annual meeting of Fellows and Members will be held at the College in Lincoln's Inn-fields on Thursday, Nov. 18th, at 3 o'clock, when the annual report of the Council will be laid before the meeting. Fellows and Members can obtain copies of the report on application to the secretary, and they can, if they wish, have their names placed on the list of those to whom the report is sent annually. Any motion intended to be brought forward at the meeting must be signed by the mover or by the mover and other Fellows and Members, and must be received by the secretary not later than Nov. 8th. A printed copy of the agenda will be issued to any Fellow or Member who may apply for one to the secretary on or after Nov. 15th.

THE WELSH COLLIERY EXPLOSION: BRAVERY OF A MEDICAL MAN.—Early on Friday morning, Oct. 29th, an explosion occurred at the Darran Colliery, about two miles from Bargoed, South Wales, where about 200 men are usually employed, but it happened that at the time of the disaster there were only 45 men at work. Rescue parties were formed, but they suffered severely from the effects of the after-damp, and several brave men lost their lives and others were overcome and prostrated. One of the first to make a heroic attempt at rescue was Dr. W. W. Turner, a medical officer, but brave though his efforts were, he was eventually overcome and was given up for dead, and although repeated efforts were made to rescue both him and others, numbers of rescuers were themselves overcome. After several hours, however, Dr. Turner was reached and found to be unconscious and suffering from injuries, but after careful attention he revived, and, we are glad to say, is progressing favourably.

CHOLERA AND TYPHOID FEVER IN RUSSIA .-Mr. Arthur W. Woodhouse, British Consul at St. Petersburg, in his annual report just received at the Foreign Office. writes: "In the whole of Russia from the outbreak of cholera in July, 1908, till the end of the year there were altogether 30,157 cases and 14,253 deaths. In the city of St. Petersburg, between Sept. 6th and Dec. 31st, there were 8763 cases and 3553 deaths. The figures in three other extensive regions of Russia for this period were as follows: Don Cossack territory, 2986 cases, 1428 deaths; Kuban territory, 1834 cases, 1025 deaths; Ekaterinoslav province, 1143 cases, 554 deaths. The last epidemic of Asiatic cholera occurred in St. Petersburg during the period 1892-95, both years inclusive, and the cases for those four years numbered 10,434. Since the 'thirties' of the last century there have been seven outbreaks of cholera here and no less than 25 years in which the epidemic has prevailed. It will thus be seen that St. Petersburg is a very hotbed of cholera, which is owing to its extremely insanitary condition. Unfortunately, since the last visitation in 1895 nothing serious has been undertaken to prevent the recurrence of the scourge, whereas in Moscow work has been slowly but continually going on in draining and improving the water-The natural result is seen in the great difference between the towns as regards the average annual mortality from typhoid. During the period 1892-1905 the average number of deaths from typhoid in St. Petersburg were between 650 and 1000, and in Moscow only 140 to 240. The following figures show the number of typhoid cases per 10,000 inhabitants in six of the principal towns of Russia and in St. Petersburg province: St. Petersburg, 164 7; St. Petersburg province, 33 9; Odessa, 55 1; Nikolaiev, 32 6; Moscow, 20 6; Sebastopol, 19.5; Warsaw, 13.2. St. Petersburg, compared with the large cities of Europe, and even of Russia, has the highest rate of mortality in general and the highest death-rate from infectious diesases. The principal cause of this, combined with the absence of modern drainage, is undoubtedly the highly defective condition of the water supply. A part of the town is still supplied with quite unfiltered water, and latest statistics show that this part is less affected by cholera and typhoid than the parts of the town in which filtered water is used. Recent analyses have proved that the filters

themselves are contaminated by the cholera vibrion, which has also been found in samples of water drawn from the intake of the supply in the river as well as at random from house-taps in various parts of the city."

BUTTER AT EXETER.—At Exeter on Oct. 23rd a butter dealer was fined £2 for selling butter containing 19 per cent. of water, being 3 per cent. above the authorised standard.

THE ROYAL HUMANE SOCIETY.—Mr. Hedley Hill, M.D. Durh., L.R.C.P. Lond., M.R.C.S. Eng., has been appointed the honorary representative of the Royal Humane Society in Bristol. Dr. Hill received the Stanhope gold medal for the best rescue in 1887.

NATIONAL DENTAL HOSPITAL AND COLLEGE.— The annual dinner of the past and present students will be held at the Trocadéro Restaurant on Friday, Nov. 19th, at 6.30 for 7 P.M. Sir Thomas Barlow, K.C.V.O., will occupy the chair.

DEATH FROM ANTHRAX.—An inquest was held at Wilsden (West Riding) recently on the body of a woolwasher who was found to have died from anthrax caused by inhalation. The Bradford Observer, in its account of the proceedings, states that the manager of the works in which the deceased man was employed gave it as his opinion that the best treatment of the dangerous East Indian wool-which the man had been handling-was to wash it without first passing it through a machine for dust extraction. The procedure he adopted was recommended by the Bradford Chamber of Commerce, and he believed it to be the common practice of the trade. Mr. G. A. Taylor, inspector of factories, asked the witness whether he did not think the regulations intended a dust extractor to be used before washing, to which the manager answered in the negative. Dr. F. W. Eurich, bacteriologist to the Anthrax Investigation Board, who gave evidence of the cause of death which the jury accepted, said that no trustworthy method of sterilising the wool before washing had yet been found. The coroner at the close of the inquest told the jury that the manager of the works was willing to adopt any modification in his system which would tend to remove the danger from his workpeople.

THE NATIONAL ASSOCIATION FOR PROMOTING THE WELFARE OF THE FEEBLE-MINDED. -The recently published annual report of this association commences with an account of the formation of fresh centres of work in many new districts. During the past year three new affiliated homes were opened, one for 20 lads at Monkton Hall, Jarrow-on-Tyne; one for 12 girls in Kentish Town, London; and one for the education of mentally defective blind persons at St. Leonards-on-Sea. In Yorkshire two new centres for special medical aid have been secured, one at Bradford and one at Sheffield. New branches of the association have been opened at Brondesbury and Bromley. In 1908 the annual conference on After Care was held at Bristol, the subjects of discussion including permanent care for mental and moral defectives, defectives in workhouses. and the detection and treatment of the feeble-minded. This year's conference was held on Oct. 28th in the Association Hall, Young Men's Christian Association, Leicester. In the morning session Dr. Astley V. Clarke presided, and papers were read on "The Health of the Community as Affected by Feeble-mindedness," "Social Dangers of Feeble-mindedness" (by Dr. G. H. Savage), and "The Home Conditions of Families where there is Mental Deficiency in One or Both of the Parents" (by Dr. Allan Warner). After-care reports were presented, and a discussion was opened by Mr. C. J. Bond of the Leicester Infirmary. In the afternoon session Lady Frederick Brudenell-Bruce presided, and papers were read on "Homes and Colonies," "The Scope and were read on "Homes and Colonies," "The Scope and Functions of the Colony" (by Dr. R. L. Langdon-Down), "Compulsion rernus Voluntary Methods," and "The Feeble-minded in America." The Girls' Home, in King Richard'sroad, Leicester, was open to visitors to the conference. The total number of boys and girls now under after-care supervision has increased from 1037 last year to 1356. The centres now at work are Birmingham, Bristol, Leicester, Liverpool, London, Northampton, Nottingham, Oldham, Plymouth, Derby, and Berkshire. In reference to the recommendations of the Royal Commission on the Care and Control of the Feeble-minded, the report states that a short summary of

them has been drawn up by Sir William Chance in the form of a leaslet published by the association, and a fuller abstract, written by Mr. W. H. Dickinson, M.P., is now appearing. The offices of the association are at Denison House, 296, Vauxhall Bridge-road, London, S.W. An urgent appeal is made for increased financial support.

Another Veronal Fatality.—Mr. W. Schröder held an inquest at Marylebone on Nov. 2nd on the body of a barrister, a resident of Harley-street, who died last week in somewhat unusual circumstances. Mr. Bernard Pitts, who lived in the same house as the deceased man, gave evidence that he had suffered for some time from insomnia and that he sometimes took drugs for its relief. On the morning of his death he came into the witness's room in an agitated state and said that he had had a "seizure" during the night. He went back to bed, where he was visited by Dr. H. P. Hawkins, who had given him previous medical advice. Deceased told Dr. Hawkins that he had taken 15 grains of veronal, a drug to which Mr. Pitts had said that the witness was very susceptible. Both medical witnesses agreed that death was due to veronal poisoning, and the coroner commented upon the frequency of such cases, saying that he thought restrictions should be placed on the sale of the drug. The chemist who supplied it said that he was sorry to say there were no such restrictions, and that its sale was increasing. In returning a verdict of "Death from misadventure" the jury recorded the opinion that the drug should only be sold on a physician's prescription.

NURSES AND MEDICAL INSPECTION OF SCHOOL CHILDREN. -Mr. A. G. R. Foulerton, medical officer of health and school medical officer in East Sussex, has presented to his education authority a memorandum on the supply of district nurses available for assistance with the medical inspection of school children. In the inspections which have taken place the necessary help has been supplied by the district nursing association affiliated with the county nursing association, by various associations not so affiliated, and by nurses provided by private individuals. Alternate proposals are outlined, but Mr. Foulerton is of opinion that the most equitable arrangement would be a modification of the scheme by which the associations providing for districts in which there are small schools only might be paid on the basis of 3s. 6d. per attendance at inspection. In the case of very large schools the sum paid per inspection might be somewhat less than the 3s. 6d. And the surplus, out of an annual grant not exceeding, say, £150, might be at the disposal of the school medical officer to provide for the attendance of a nurse from a distance when a nurse could not be obtained locally. It was estimated that the annual expenditure under this scheme would be something less than £150, but for this sum a very efficient scheme could be instituted. The education authority adopted the memorandum authorising the expenditure at the discretion of the medical inspection subcommittee. There are 175 schools and 24,657 scholars in the East Sussex education authority's area and the satisfactory attitude of parents generally towards the medical inspection of their children has been very marked.

CENTRAL MIDWIVES BOARD .- A special meeting of the Central Midwives Board was held at Caxton House, Westminster, on Oct. 28th, with Dr. F. H. Champneys in the chair, to consider what action should be taken as to the recommendations of the Midwives Act Committee. Board passed the following resolutions, which in its opinion any amendment of the Midwives Act, 1902, in the light of the recent report, is to provide for :-

Adequate and certain remuneration of medical practitioners called in, Adequate and certain remuneration of medical practitioners called in, under the Board's regulations, to assist midwives. More definite powers of "suspension" of midwives, whether by the local supervising authority or by the Central Midwives Board. Subvention from public funds of midwives who are unable to maintain themselves in sparsely populated and poor districts. Revision of the constitution of the Central Midwives Board so as to afford two representatives, to be chosen without restrictions, of the Midwives Institute. Systematic purging of the Midwives Roll. That the right of delegation of their powers under the Act by the local supervising authorities should be revoked.

The Board resolved to commit these resolutions to a committee with instructions to prepare a report thereon to be submitted to the Board.—An ordinary meeting of the Board was also held on the same date at the same place. A letter was received from the Lord Mayor of Manchester, forwarding

a copy of a resolution passed by the Manchester city council, suggesting that the Municipal Corporations Association should be represented on the Central Midwives Board. A letter was considered from Mr. G. A. Clarkson of Caterham, complaining of the conduct of a certified midwife. The Board decided that Mr. Clarkson should be informed that as the midwife was acting at the time of complaint as a nurse and not as a midwife the matter is not within the scope of the Board's jurisdiction. A letter was considered from the Monmouthshire Nursing Association petitioning the Board to establish an examination centre at Cardiff, or in the alternative to permit the written examination to be held at Newport. The Board decided that the Monmouthshire Nursing Association should be informed that the question is under consideration by the Board. The Board having considered the application of the midwife Ann Kirk, who had applied for the voluntary removal of her name from the roll on the ground of inability to comply with the rules, decided that the application should be accepted, and that the secretary should be directed to remove her name from the roll and to cancel her certificate.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Parliamentary Session.

THE Parliamentary session will still last for several weeks. After passing the Finance Bill the House of Commons will take a holiday of a fortnight. The interest in the Budget proposals will then be transferred to the House of Lords. According to present arrangements, the debate on the second reading there will not begin until Monday, Nov. 22nd. Should the Peers refuse to give their assent to the measure. a contingency which Parliamentary opinion now regards as probable, a general election is inevitable. However, the appeal to the constituencies cannot well be made until after Christmas. The intervening time will be devoted to strenuous political propaganda in the country by all parties. Everyone engaged at Westminster has felt the strain of the prolonged Parliamentary deliberations.

The Housing and Town Planning Bill.

At the instance of the President of the Local Government Board the House of Commons has accepted a number of the amendments made by the House of Lords in the Housing and Town Planning Bill. Those which the Commons have declined to accept are those which Mr. BURNS considered to have a highly prejudicial effect on the working of the measure. For instance, the right honourable gentleman strongly insisted on the need for the prohibition of the construction of backto-back dwellings. The Lords inserted a provision allowing them under certain conditions. Mr. Burns, however, denounced them as insanitary and the nurseries of tuberculosis. On his motion, the Commons disagreed with the Lords' amendment on this point.

The debate on the Lords' amendments occupied a prolonged sitting of the House. It was not until about 2 o'clock on Tuesday morning that the changes which had been made in the House of Lords in the clause dealing with the appointment of county medical officers of health came up for review. It will be remembered that the Lords struck out the subsection that the Local Government Board might by order prescribe the duties of medical officers of health appointed by a county council under Section 17 of the Local Government Act, 1888, whether before or after the passing of the Bill. The President of the Local Government Board did not advise the House to insist on the phraseology of the subsection. He moved to insert another one on somewhat modified lines. It was to the effect that the duties of a medical officer of health for a county should be such general duties as might be prescribed by the Local Government Board and such other duties as might be assigned to him by the county council. This subsection was carried by 77 votes to 25. By 75 votes to 23 the House disagreed with the Lords' amendment which struck out the subsection which set out that a medical officer of health of a county should be removeable by the county council, with the consent of the Local Government Board and not otherwise. The House of Lords will thus have an opportunity of reconsidering their decisions, by which two important provisions of the clause dealing with county medical officers of health were excised.

Poor-law in Scotland.

The report of the Royal Commission on the Poor-law with regard to Scotland has just been issued as a Parliamentary Blue-book.

HOUSE OF COMMONS.

THURSDAY, OCT. 28TH.

Enteric Germ Carriers in the Army.

Captain CLIVE asked the Secretary of State for War whether the supposed enteric germ-carriers were still being detained in military hospitals and subjected to experimental medical treatment, and when he proposed to publish a further report on the success, or want of success, of this treatment.—Mr. HALDANE replied: The Army Council has

decided that germ-carriers shall be treated for three months in hospital on arrival in England, and if not cured at the end of that time will be given the option of remaining in hospital for further treatment. If they decline further treatment they will be discharged from the service. Consequent on this decision the men now at Netley will be discharged from the service if they decline further treatment. The second report on the carriers will shortly be published.

Sanitation in India.

Sanitation in India.

Dr. Rutherford asked the Under Secretary of State for India whether, in view of the Viceroy's statement on Oct. 12th at Simia that the deaths from fever in India during the last ten years averaged nearly 4,500,000, and that last year the deaths were 1,000,000 over the average, and the increase was believed to be due to malaria, he could say how much money was allocated by the Government of India in 1°93 and 1908 to sanitation.—The Master of Elibark answered: The expenditure on sanitation is not recorded under one head in the accounts, as officers of various departments are engaged in work intended to improve the health of the people. I have therefore grouped together as representing expenditure of this nature the outlay shown in the Government accounts under the head "Medical," the outlay shown in the same accounts under the head "Civil Works." for hospitals, dispensaries, drainage, waterworks, and similar objects, and that shown in the accounts of municipalities and other local bodies under the heads "Medical," "Conservancy," "Water-supply," and "Public Health and Convenience." The total expenditure under all these heads amounted to £29,5000 in 1897-93 and £4,455,000 in 1897-98. I may add that a special permanent grant of £200,000 a year was made in 1908-09 by the Government of India to provincial governments to be used for additional expenditure on sanitary purposes.

Mr. Refs also asked the honourable gentleman whether he had any official information showing that the diminution of deaths from malaria necessarily followed upon improved sanitation, or whether it was still doubtful if improved sanitation materially lessened mortality from malaria; and whether the Secretary of State had any figures in relation to those matters which he could lay before the House.—The Master of Elibark replied; The Secretary of State had any figures in relation to those matters which he could lay before the House.—The Master of Elibark replied; The Secretary of State sees no reason to doubt the conclusion of

and other circumstances

Cleansing of Persons Act.

Sir WILLIAM COLLINS asked the President of the Local Government Board how many local authorities in the United Kingdom, exclusive of London, and in the County of London, respectively, had taken action under the Cleansing of Persons Act; whether any representations had recently reached him suggesting that more extensive use should be made of the powers given under this Act; and what action, if any, he proposed to take in the matter.—Mr. Burns wrote in reply: I have no jurisdiction under the Act referred to, and am not in possession of any complete information as to its administration. I have recently received a communication from the coroner to the City of London stating that a jury had added to their verdict a rider to the effect that in their opinion the time had arrived when the Act, instead of being merely adoptive, might with advantage to the public be made compulsory. I am not in a position at the present time to promise to introduce the legislation which would be necessary to give effect to this suggestion.

Monday, Nov. 1st. Cleansing of Persons Act.

MONDAY, Nov. 1st.

Cesspools in Croydon Rural District.

Mr. WILLIAM THORNE asked the President of the Local Government Board whether he could say what number of cesspools now existed in the Croydon rural district area; whether, as a result of the additional powers which had been conferred upon the Croydon Rural District Council, according to his statement in the House on July 27th, the number of cesspools had been reduced; and, if not, whether, in view of the seriousness of the existence of cesspools within water-supply areas, as was evidenced by the case of Gravesend in the report of Dr. Reece to the Board, he would say what action the Board would take in the matter.

Areas, as was evidenced by the case of Gravesend in the report of Dr. Recec to the Board, he would say what action the Board would take in the matter.

The honourable Member also had another question on the notice paper in which he asked the right honourable gentleman whether, in view of the seriousness of the menace to the public health of Groydon by the existence of cesspools in the Croydon rural district area, as stated in the reports of the medical officer of health for the borough and the borough engineer, he would request the Croydon Rural District Council to cause reports to be made to them by the medical officer of health, surveyor, or inspector of nuisances of the rural district on the question and the extent of the danger, so that the rural district on the question and the extent of the danger, so that the rural district on the question and the extent of the danger, so that the rural district on the question and the extent of the danger, so that the rural district and that approximately 400 properties drain into cesspools. Of these 270 are outside the areas in respect of which there is an agreement between the councils of the borough and of the rural district for the reception of the sewage into the sewers of the corporation, and these houses are stated to be for the most part in rural portions of the district and at a considerable distance from an outfall sewer. In one parish, Woodmansterne, it is stated that there is urgent need for main drainage for about 90 houses near the boundary of Coulsdon which could be connected with the borough sewers, but this parish is outside the area from which the corporation receives the sewage, and I am informed that it refuses to extend these areas except upon terms which the district council is unable to accept. The rural district council, which has spent some £220,000 on works of sewerage and sewage disposal, has schemes already sanctioned or in course of preparation in respect of 70 of the properties in the parishes of Beddington, Coulsdon, and Sanderstead, parts

to in the second question of my honourable friend, and I have requested that this may be done.

The Care and Control of the Feeble-minded.

The Care and Control of the Feeble-minded.

Answering Mr. Henry Walker, Mr. Asquire the Prime Minister stated that the Government were alive to the importance of the recommendation of the Royal Commission on the Care and Control of the Feeble-minded in favour of taking out of the Poor-law all classes of mentally defective persons and of removing the feeble-minded from the workhouse. However, he would refer the honourable Member to the statement made by the Home Secretary on August 31st last in reply to a deputation. The Home Secretary on that occasion said that though there might be considerable difficulties in the way of legislation he was in agreement with the deputation as to the importance of the subject, and that he had ascertained that the Lord Chancellor was of the same opinion. And he added that he hoped to be able to make a practical effort next session in the direction of legislation.

Tunhoid Feers in Levis.

Typhoid Fever in Lewis.

Typhoid Fever in Lewis.

Mr. Weir asked the Lord Advocate whether, in view of the outbreak of typhoid fever in the townships of Borve and Lower Shader, island of Lewis, which continued from January to June last and was attributable by the medical officer to the insanitary condition of the townships, he would state whether arrangements had yet been arrived at under which sites might be secured in suitable positions, especially bearing in mind that Dr. Dittmar, the medical inspector for the Local Government Board for Scotland, in his report published in April, 1905, strongly condemned the condition of the Lewis townships.—Mr. Ure answered: In this case the outbreak is attributed, as to a probable cause, to the contamination from surface wells. Steady progress is being made by the district sanitary authority with such resources as they have at their disposal in improving the water-supply.

THESDAY, Nov. 2ND.

TUESDAY, Nov. 2nd.

The Use of Antitoxin in Public Hospitals.

The Use of Antitoxin in Public Hospitals.

Mr. Lupton asked the President of the Local Government Board whether he was aware that during the 13 years 1895-1907, at the hospitals of the Metropolitan Asylums Board, there were 63 249 cases of diphtheria treated with antitoxin; that 8917 of these cases died, being a case-fatality of 14 per cent.; that in the same hospitals, in the same period, there were 11,716 cases of diphtheria which were not treated with antitoxin; that 703 of these cases died, being a case-fatality of 6 per cent.; and that out of these 703 deaths 55 were considered hopeless on admission to hospital; and whether he would recommend legislation to stop the use of antitoxin in public hospitals.—Mr. Burns replied: I am aware of the figures to which my honourable friend refers and which appear to be derived from the annual report of the managers for 1907. No comparison, however, can properly be drawn between the death-rate of patients treated with antitoxin and that of patients not so treated. The latter class consists largely of persons suffering from a mild form of diphtheria, who were not ill enough to require the special treatment, and, indeed, the few deaths that occur in this class are almost entirely those of patients who were too ill, or who came into hospital at too late a stage in their illness, to derive any benefit from the injection of antitoxin. I could not undertake to adopt the suggestion in the last part of the question.

The Importation of Unsound Fat.

The Importation of Unsound Fat.

The Importation of Unsound Fat.

Mr. Morton asked the President of the Local Government Board whether quantities of fat obtained from diseased pigs and other unsound meats which had been condemned by the authorities in America were imported into the United Kingdom without being artificially coloured or otherwise denatured; whether, in the circumstances, this material could be supplied to makers of lard or other foods in this country; and, if so, what action he proposed to take to prevent this matter from being used in the preparation of food.—Mr. Burns answered: I understand that it is the case that consignments of food of the character indicated in the question are imported into the United Kingdom. The fat has not been denatured, although in conformity with the American regulations it is imported in containers with whitened ends on which the nature of the contents and words indicating that they are not for human consumption appear. There is, however, some risk of this material being obtained by lard refiners in this country, and the matter has received the attention of my department and of medical officers of health at the ports of importation. Under the regulations issued last year under the Public Health (Regulations as to Food) Act, 1907, consignments of the material in question have been detained at the port of entry until satisfactory guarantees have been given that they are to be used for industrial purposes (such, for instance, as soap making) only. as soap making) only.

Gaelic Warnings against Infection.

Mr. Wrir asked the Lord Advocate whether leaflets giving directions how to prevent and cope with the different infectious diseases, including consumption, had yet been printed in Gaelic as well as English, and circulated in the townships in the island of Lewis and other congested areas.—Mr. Ure replied: The answer is in the affirmative.

The Medical Services in India.

The Medical Services in India.

Mr. Hazleton asked the Under Secretary of State for India whether the higher grades of both the civil and military medical services in Native States were usually filled by Indians to the entire satisfaction of the Government and the people; whether similar posts outside these States were held by officers of the Indian Medical Service at much higher salaries; and, seeing that this latter system led to extravagance, inefficiency, and discontent, whether he proposed to abolish it by filling these places as in the Native States. The Master of Elbaks wrote in reply: So far as the Secretary of State has information on the subject, in the 25 most important Native States the headship of the medical department, with six exceptions, is held by an Indian. In the six mentioned the head is an officer of the Indian Medical Service, but in 16 of the remainder there is an agency surgeon, whose advice is doubtless available to the Durbar in medical matters. He has no information as to other medical appointments in these States, and has not heard that any dissatisfaction with them has been expressed. As to the system in force outside these States and the measures being taken in connexion therewith, I would refer my honourable friend to the papers recently laid upon the table of the House.

Wednesday, Nov. 3rd.

WEDNESDAY, Nov. 3RD.

The Naval Medical Service.

Dr. V. H. RUTHERFORD asked the First Lord of the Admiralty

whether the committee which was appointed to inquire into certain ricumstances affecting the medical service in the navy had reported yet; and, if so, whether he would lay the report upon the table of the House.—Mr. McKenka replied: The report of the committee, which is receiving our earnest attention, is a long one, and as it includes recommendations dealing with numbers and organisation for war, it is not practicable yet to say whether it can be made public in whole or in part.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to TRE LANGET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratutious publication.

ADAMS, J. E., M.B., B.S. Lond., F.R.C.S. Eng., has been appointed Assistant Surgeon to the East London Hospital for Children.

BLACKWOOD, WILLIAM, M.B., Ch.B. Edin., has been appointed Honorary Medical Officer to the Camborne (Cornwall) Dispensary.

BOWEN, W. H., M.S. Lond., F.R.C.S. Eng., has been appointed Surgeon BUCK, A. H., F.R.C.S. Ed., M.R.C.S., L.R.C.P. Lond., has been appointed Senior Honorary Surgeon to the Sussex County Hospital. to the East London Hospital for Children.

CLARKE, HENRY J., Jun., M.B., B.C. Cantab., M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Surgeon to the Doncaster Royal 1.1ftrmary.

Lond., has been appointed Honorary Surgeon to the Doncaster Royal Listimary.

Dockbar, J. S., M.D., Ch.B. Vict., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Bishop Stort-ford District of the county of Hertford.

FLETCHER, H. N., M.B., B.S. Edin., has been appointed Senior Assistant Surgeon to the Sussex County Hospital.

GARDINER, PETER, M.D., C.M. Glasg., D.P.H. Lond., has been appointed Honorary Medical Officer to the Camborne (Cornwall) Dispensary.

HOARE, EDWARD F., M.D., Ch.B., L.S.A., has been appointed Honorary Assistant Surgeon to the Cancer and Skin Hospital, Liverpool.

KELLIE, KENNETH, M.B. Cantab., M.R.C.P. Lond., has been appointed an Assistant Physician to the Royal Hospital for Diseases of the Chest, City-road.

MCLAREN, MAUD V. EVERETT, L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Part-time Medical Officer to the School Board of Glasgow.

Glasgow,
OLEY, GEORGE H.,

Glasgow,
POOLEY, GEORGE H., F.R.C.S. Eng. & Edin, has been appointed
Lecturer in Ophthalmology in the University of Sheffield.
THOMAS, JOSIAH TELFER, L.R.C.P. Lond., M.R.C.S., has been
appointed Medical Officer to the Camborne (Cornwall) Dispensary.
TONKING, JOHN HERBERT, M.B. Lond., L.R.C.P. Lond., M.R.C.S., has een appointed Honorary Medical Officer to the Camborne (Cornwall)

Dispensary.

VERRALL, T. J., M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Consulting Surgeon to the Sussex County Hospital.

WILKINSON, GFORGE, M.B Cantab., F.R.C.S. Eng., has been appointed Lecturer in Diseases of the Ear, Nose, and Throat in the University

Pacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BANBURY, HORTON INFIRMARY .- House Surgeon. Salary £80 per

Births, Marriages, and Deaths.

BIRTHS.

BOYER.—On Nov. 1st, at Temperley, Buenos Aires, Argentine Republic, to Mr. and Mrs. Louis J. Boyer, a daughter. (By cable.)
COUTTS.—On Oct. 27th, at Surrey-street, Norwich, the wife of D. K. Coutts, F.R.C.S., of a daughter.
FRASER.—On Oct. 31st, at Coldharbour-lane, S.E., the wife of D. H. Fraser. M.A., M.B., B.C. Cantab., of a son.
HYDE.—On Oct. 31st, at Vine House, Kingston-on-Thames, the wife of Reginald Hyde, M.R.C.S., L.R.C.P., of a daughter.

MARRIAGES.

BATHURST—WILLIAMS.—On Oct. 14th, at St. Augustine's, Penarth, Lacey Bathurst, M.B., B.S., of Leeds, son of C. Lacey Bathurst, of Sydenham, to Gwendoline Isabel Victoria, fourth daughter of Williams Edgar Williams of Cardiff.

HANNE—MORISON. On Oct. 30th, at Holy Trinity, Paddington, by the Ven. Archdeacon A. T. Scott, Vicar of St. James, Tunbridge Wells, assisted by the Rev. Cecil White, Vicar of Holy Trinity, Paddington, Louis Brightwell Hayne, M.D., of Harrogate, second son of Henry Hayne, Tunbridge Wells, to Margaret Lillias Morison, daughter of the late Murdoch Shaw Morison and of Mrs. Morison, of 17, Orsett-terrace Hyde Park.

daughter of the late Murdoch Shaw Morison and of Mrs. Morison, of 17. Orsett-terrace Hyde Park.

HIND-BIGG-WITHER.—On Oct. 26th, at St. Mary's Church, Shalford, near Guildford, Henry Hind, F.R.C.S., to Helen, only daughter of Colonel and Mrs. A. C. Bigg-Wither, of Tilthams, Godalming.

INMAN-WETHERED.—On Nov. 2nd, at St. Marylebone Parish Church, by the father of the bridegroom, assisted by the Rev. W. D. Morrison, LL. D., and the Rev. W. Burnaby, Arthur Conyers Inman, M.B. son of the Rev. H. T. and Mrs. Inman, of 69, Warwick-road, Kensington, to Dorothy Marguerite, daughter of Dr. F. J. and Mrs. Wethered, of 83, Harley-street, W.

DEATHS.

CAMERON.—At Cleethorpes, on October 23rd, Alexander Cameron, M.D., late of Caistor, aged 68.

HAYER.—On Oct. 2nd, at Mafeking, South Africa, William Andrew Hayes, M.R.C.S., L.R.C.P., aged 46 years.

N.B.— A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Aotes, Short Comments, and Answers to Correspondents.

THE RULES OF THE NORFOLK AND NORWICH HOSPITAL IN 1771.

A CORRESPONDENT has forwarded us a copy of the original "Rules and Orders" for the Norfolk and Norwich Hospital, the history of which we recently described, and it is interesting to note that the regulations of a provincial hospital in 1771 did not greatly differ from those in force in many similar institutions at the present day. There were in all 92 rules, of which 35 concerned the government and regulation of the hospital, 16 the admission and discharge of patients, 7 the physicians and surgeons, 8 the apothecary, 4 the secretary, 7 the matron, 2 the servants, 2 the porter, and 11 the patients. The system of governors "letters" for in- and out-patients respectively, whereby every subscription or donation entitled its giver to recommend a number of patients in proportion to its amount for hospital treatment, is still in force very generally, and we know of county hospitals in which the rule still exists that the patients shall attend to be admitted once a week except in cases of extreme urgency. Neither has the tradition that no capital operation shall be performed without a consultation of the whole of the honorary staff been yet universally rescinded, although this rule, like the last, where it still exists, is generally regarded as a dead-letter. The functions of the general and weekly boards of governors in no way differed in the eighteenth century from those of the corresponding bodies to-day, and in the weekly house visitors we see the direct prototype of the modern house committees, although they performed their duties in a more ceremonious manner than is usual at present. We read in Rule XVIII., "That two or more Governors be appointed at every weekly Board to visit the House once every day for the ensuing week: that they walk through the Wards with White Wands in their hands, that they may be known to be the House Visitors, and that, as soon as they enter the Wards the Nurses withdraw, and the Patients attend at their respective Beds: that they inquire of the Patients, whether the Physicians, Surgeons, Apothecary, Matron, Nurses, and Servants have attended them agreeably to the Rules of the Hospital: whether the Provisions were good, and have been properly weighed and distributed: that in their return from visiting the wards the Apothecary, Matron, Nurses, and Servants be ready to attend them, to answer their Questions: that the Visitors inquire of them, whether the Patients have been guilty of swearing, drinking, or any indecent or irregular behaviour etc." These duties closely approximate to those of modern house committees, but perhaps it is as well that the white wands are dispensed with in an age that has quite forgotten "the nice conduct of a clouded cane." Amongst the cases ineligible for admission were "Women big with Child, Persons in Consumptions, or subject to Epileptic Fits, suspected to have the Small-pox, Venereal Disease, Itch, or other Infectious Disorders." The visiting staff then, as now, was honorary, and the resident medical officer was known as the "apothecary." That official had little discretion in the treatment of cases except in cases of great emergency. He was not allowed to practise out of the hospital and he must "be home at 10 of the clock at night at farthest, and do not lie out of the house without special leave, and must always acquaint the matron where he is to be found." is to be found." He was, however, allowed to order about the messenger or porter, which appears to have been his only privilege as far as we can find from the rules. Each physician was allowed to take two pupils who might dress the patients under the directions of their master but might not prescribe for any case. The duties of the nurses were summed up in two rules, one ordering them to clean the wards before 7 o'clock in summer and 8 o'clock in winter, and the other running as follows: "That the Nurses and Servants obey the Matron as their Mistress, and that they behave with tenderness to the Patients and Civility and Respect to Strangers," on whose charitable pockets the governors responsible for the injunction doubtless had their designs.

THE ORIGINAL HOME OF SMALL-POX.

In his curious "Sermon against the Dangerous and Sinful Practice of Inoculation," which was preached at St. Andrew's, Holborn, in July, 1722, the Rev. Edmund Massey, one of the City "Lecturers," gave it as his opinion that the disease with which Satan was allowed to afflict Job was none other than confluent small-pox. "The Devil," said the preacher, "by some venomous infusion into the body of Job, might raise his blood to such a ferment, as threw out a confluence of inflammatory pustules all over him from head to foot." Hence, of course, the "sore bolls, from the sole of his foot unto his crown," described in scripture. The preacher did not see what could be advanced to invalidate this supposition, especially as inoculation came from the East-a fact proving that small-pox is of oriental origin too.

Old commentators, however, including Greding, who discussed Massey's view in 1781, held that the disease which afflicted Job was a form of Syrian ulcer.

The author of the Book of Job probably wrote at a late epoch B.C., and described a disease actually observed by him among patriarchal tribesmen to the east of Judea. Modern research has traced the small-pox to Arabia and African countries bordering on the Red Sea, on its westward progress from India and China. Tabari, the best of the Arab historians, is quoted by Dr. Creighton as recording an oral tradition, according to which small-pox appeared for the first time in Arabia in what was known as the Elephant War in 5-9-571 A.D. It is said to have broken out among the Abyssinians be leging Mecca, and that the disease probably crossed the Red Sea and was held to be air-borne is implied in an Arab legend as to its origin, according to which flocks of birds, coming up from the sea, dropped stones from their beaks and claws upon the Abyssinians. These stones produced wounds and pustules.

At about the period of the Elephant War the Justinian plague was raging in Europe. It had originated in about the year 543 A.D., when it decimated Constantinople, and it seems to have appeared sporadically in Northern Italy and Southern France, where its symptoms are described by Gregory of Tours. He calls it "lues inguinaria," a phrase which suggests bubonic plague. The exact nature of the plague of Justinian's time is, indeed, doubtful. And we are therefore not justified in supposing that it was an early epidemic of small-pox. This disease, indeed, very probably only appeared as an epidemic in Europe at the time of the earliest Saracenic invasions, though the international trade and intercourse of the Roman Empire may have introduced isolated cases of it at an earlier date. It was essentially the Saracenic disease, and was first described by the Arab physicians

THE NATIONAL FOOD REFORM ASSOCIATION.

Some interesting particulars regarding the history and work of the National Food Reform Association are given in the newly published first annual report. The association was inaugurated at a meeting held at 54, Mount-street, London, W., by invitation of the Countess of Plymouth on Feb. 26th, 1908. On this occasion a resolution was adopted to the effect that the meeting, profoundly conscious of the importance of diet as a factor in the moral, intellectual, physical, political, and economic life of the nation, believed that the time was ripe for a new step towards a more rational and humane system. Many well-known names both of ladies and gentlemen appeared on the list of the committee, a pamphlet entitled "Reasons for Food Reform" was published, and various letters and articles were inserted in the daily press. Since March last six booklets have been published, two of them being collections of recipes for the preparation of fleshless dishes. One of these (booklet No. 2, with 24 simple recipes) was sent to the heads of more than 500 of the leading public and private schools for both sexes, to the Colleges at Oxford and Cambridge, to the whole of the Social Settlements in the United to the London hospitals, and to similar institutions. Several of the publications of the association can be recommended to those who may be desirous of reducing the proportion of animal food in their dietary. The secretary of the association is Mr. Charles B. Hecht, and the offices are at 178, St. Stephen's House, Westminster Bridge, close to the Houses of Parliament

VERMINOUS PERSONS.

Dr. Waldo held an inquest on Oct. 25th on the body of Edward William Brighton, aged 47 years, of no home, who was found in a dying condition on the Thames Embankment and died a few hours later at the City Branch Infirmary. It was stated that in 1904 the man's mother died, leaving him £350, and he spent the whole of this money in drink, drawing the last instalment in June last. A police constable said that he had known some of these homeless people to sit on the Embankment for two days and two nights without going away. When moved on by the police they would simply go to the next bench.

Usually they brought a store of food with them. Death having been certified to be due to organic disease, caused by alcoholism and accelerated by exposure and self-neglect, the jury returned a verdict accordingly, adding a rider expressing their opinion that, in the interests of public health, the police should have power to insist on homeless people being cleansed when necessary, and further, they considered that the Cleansing of Persons Act, 1897, which is at present an optional one, should be made compulsory. The Act of 1897 provides that any local authority shall have the power, when in their discretion they shall see fit, to permit any person who shall apply to them, on the ground that he is infested with vermin, to have the use, free of charge, of the apparatus (if any) which they possess for cleansing the person and his clothing from vermin. The use of such apparatus shall not be considered to be parochial relief or charitable allowance to the person using the same or to the parent of such person, and no such parent or person shall by reason thereof be deprived of any right or privilege or be subject to any disqualification or disability. Local authorities may expend any reasonable sum on buildings, appliances, and attendants that may be required for the carrying out of this Act, and any expenses for these purposes may be defrayed out of any rates or fund applicable by the authority for general sanitary purposes, or for the relief of the poor. There can be no question that it is a standing disgrace to our modern civilisation and our laws that thousands of verminous and filthy persons should be allowed to roam the highways of our great cities and infect the benches and grass in our public parks without the police or sanitary officers having any power to interfere with them, seeing that they

are infective in every sense of the word. It would be interesting to have statistics as to the number of persons in a year who apply to the local authorities throughout England to have themselves and their clothing disinfected. For the sake of the public health, and more particularly for the sake of the children of the respectable poor using the seats and grass in our public parks, it seems desirable that the police should have powers to detain verminous persons for their compulsory disinfection. But since poverty is at the bottom of their condition it is to be feared that relapses into filth would always be common.

PROFESSIONAL AMENITIES.

To the Editor of THE LANCET.

SIR,-In your account of the discussion of the paper read by Dr. F. Hewitt before the Medical Society of London, Dr. J. Vincent Bell is reported to have said "the dentist was often found to be more expert in giving an anasthetic for a dental operation than the raw country practitioner." What have that hard-working and very often extremely capable body of men, the country practitioners, done to merit such a term of opprobrium? Cannot the amenities of discussion be observed without using terms of reproach to professional brothers? On reading the reports of discussions of some societies of which the members relegate to themselves special skill, I have often been struck by the fact that apparently none but fools and dunderheads enter the ranks of the general and country practitioner—a sentiment as untrue as it is little creditable to the medical profession.

I am, Sir, yours faithfully,

T. W. S. PATERSON, M.A., M.B. Cantab. Holland-park, W., Nov. 1st, 1909.

MORALITY AND HEALTH.

In the form of a lecture delivered at the Nurses' Lodge last week the Hon. Albinia Brodrick repeated the substance of her paper read at the Nursing Conference in July on Morality in Relation to Health. The subject is essentially a difficult one for public discussion, but Miss Brodrick dealt with it in a straightforward and scientific manner, urging from the start the importance of facing squarely a fact which exists, and the criminality of preserving wilful blindness to what amounts to a grave social and national danger. To nurses and all those engaged in any form of health or social work an accurate knowledge of these matters is especially valuable, as the lecturer showed when she quoted the instance of a healthy young girl who was taken to a rescue home and was put to sleep in soiled sheets, gonorrhœal infection resulting. Nurses possess unique opportunities of helping and advising their women patients both as regards their own health and in the training of their boys. The education and discipline of the young by the parents was a point upon which great stress was In describing the chief symptoms and sequelæ of the common forms of venereal disease the lecturer urged that it was only by means of widespread knowledge that the evil could be stamped out. The highly infectious nature of these es is probably known to but few outside the medical profession, and in the present condition of society the lips of medical men are sealed and the innocent continue to suffer with, or more than, the guilty. "Syphilis insontium," said the speaker, "crowns the mystery of pain." Among the suggestions for the prevention of the spread of venereal disease compulsory notification was recom-mended, and in order to obtain better statistics the frank inclusion of venereal disease on death certificates. Attention was also drawn to the very small accommodation in this country for the free treatment of disorders classed under this heading.

We understand that a committee is to be formed with the object of furthering prophylactic measures against venereal disease, especially educational measures, and the cooperation of medical men is naturally desired by the promoters of the movement so courageously started by Miss Brodrick, who has been asked to lecture in several provincial towns on the "national evil." The matter is, of course, one of the utmost difficulty to bring to the proper attention of the public. Those who most need enlightenment are the vicious and careless who would be the last to listen with any respect to the earnest words of a band of social reformers who will have difficulty enough in overcoming the prejudices of a number of "respectable people. But we think such a movement may be powerful for good in educating the ignorant before they have drifted into bad habits. There can be no greater inducement to chastity than a thorough knowledge of the terrible physical co-sequences that may arise from its neglect. The movement accordingly has our sympathy, and those interested in the propaganda can obtain Miss Brodrick's lecture, which we have summarised above, in pamphlet form from The Free Press, 11, Adam-street, London, W.C.

THE ILFORD X RAY PLATES.

In the course of a visit to the Annual Exhibition of the Royal Photographic Society held at the New Gallery, Regent-street, W., we were shown some excellent radiographs illustrating pulmonary disease and others which had been made with the special X ray plates of Messrs. Ilford, Limited. We have had occasion to refer to the good qualities of their X ray plates in previous issues, and it is satisfactory to find that the quality is better than ever. The great characteristic of the Ilford X ray plate is the ease with which a satisfactory density is secured, as well as a great richness of detail; and these good qualities

are readily obtainable with very short exposures. The particular plates we examined suffered somewhat from over-development, but apart from this various stages of pulmonary tuberculosis were shown with striking clearness. One showing a cavity in the apex of the lung, the thickened wall of which comes out very distinctly, is particularly worthy of notice. Messrs. Ilford, Limited, have done a real service in placing such an excellent X ray plate in the hands of radiographers. A satisfactory feature is that we are now independent of any supplies from abroad.

Post-Graduate.-We have often pointed out the general merits of the classes, but we think we could hardly select in our columns special classes for particular eulogy.

Anonymous.—We are obliged for having our attention drawn to the swindling advertisement. The stuff will be analysed in our laboratory.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, Nov. 4th, 1909.

At the Royal Bye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed suchsively "To THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is derivable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTI-FIGATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES. TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are :-

FOR THE UNITED KINGDOM.
One Year £1 12 6
Six Months 0 16 3
Six Months 0 18 2
Three Months 0 8 2
Three Months 0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANGET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—The Manager, The Lancet Offices, 423, STRAND, LONDON, ENGLAND.

affords a ready means of finding any notice but is in itself an additional advertisement.

Advertisements (to insure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in The Lancer.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only

should be forwarded.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Adver-

tisements are also received by them and all other Advertising Agents.

Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager,

Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

In Address

THE NATION AND THE TROPICS

Delivered at the London School of Tropical Medicine on Oct. 26th, 1909,

BY WILLIAM OSLER, M.D., F.R.S.,

REGIUS PROFESSOR OF MEDICINE, OXFORD.

[SPECIALLY REPORTED IN FULL FOR THE LANCET.]

GENTLEMEN, - The evolution of our present hopeful condition, like that of organic life, looks uniform; but examined more closely this uniformity disappears in a deeper parallel —the sudden intrusion of apparently new forces which have changed the broad surface of humanity quite as profoundly as did, for example, the glacial period the biology of the northern portions of the globe. Three outstanding events have loosened as a spring the pent-up energies of the modern world—the Greek civilisation, the geographic renaissance of the sixteenth century, and the scientific awakening of the nineteenth century. Greek thought not only stripped man for the race, but Greek methods gave him correct principles of training and clear ideas of the nature of the race to be run. Collectively we follow to-day occidental, Greek ideals, and what makes Western civilisation such a tissue of inconsistencies is the injection, Anno Domini of an oriental morality which controls the individual, while powerless to sway the nations. The geographic renaissance has given to the progressive peoples of Europe a new pinnacle of outlook. To the lust of conquest succeeded the lust of commerce, to be followed by the burning zeal to evangelise; and then a steady, sober plan of settlement which has encircled the earth with new nations. And the third great outburst of energy is the scientific awakening of the nineteenth century, which has not only placed in his hands a heretofore undreamed of capacity for material progress, but has given to man such a control of nature that at a stroke is removed the chief obstacle to a world-wide dominion.

The expansion of modern Europe, the completion of which was one of the great features of the latter part of the nineteenth century, has opened a broader vista than ever before looked on by humanity. The ascent of man began in the tropics, where the conditions of nature made life easy, and at least four of the six great ancient civilisations—the Egyptian, Phœnician, Assyrian, and Babylonian-rose and fell within, or close to the tropics. Once only in modern times has a tropical people, reaching a high grade of civilisation, spread far and wide, in the magic outburst with which the Arabians shook the very foundations of Christianity. In the last four centuries the expansion of Europe has changed the map of the world, and in conflict with the old civilisations in North and South America, and by wholesale appropriations in Asia and Africa, the children of Japhet have gone forth with the Bible in one hand and the sword in the other conquering and to conquer, taking the uttermost parts of the earth for their possession. In the course of this period they have partitioned among them one hemisphere, two continents, and a large part of a third. A glance at the map shows that as a result of this expansion many independent nations have sprung up; but a very large portion of the conquered earth is still in control of Europe, and linked to it by strong political ties. Practically these countries come in two divisions—the self-governing colonies and the dependencies. A majority of the former are in the temperate regions, and have reached a stage of maturity, and one of them has become the great nation whose representative honours us to-day with his presence.

Scarcely less important, and vastly greater in extent and population, are the dependencies, nearly all of which fall within the tropics, and with their destiny the problem of the twentieth century is bound up. If we take two lines, 30 degrees north latitude and 30 degrees south latitude, the part of the earth between represents the great heat belt of the tropics, within which lie the whole of Africa, Arabia, India, Burma, the Malay States, Polynesia, the Philippines, Mexico, and the Central American Republics, with the West Indies. Mr. H. O. Becket of the Department of Geography, Oxford, has prepared for me four maps (which I have much No. 4498.

pleasure in presenting to the school) showing at a glance the tropical possessions of the four Western nations—England, France, Germany, and the United States. The following table gives the figures in population and in square miles of territory:—

_ • {	Т	ropical ter	Total	Home country.		
	America.	Africa.	Asia.	Pacific.	tropical.	country.
France }	•	17,700,000 4,032, 00 0		90,000 9,000		
German (Empire)	Nu.	11,700,000 931 ,5 00	4736.	400,000 96,000		
United; Kingdom }		30,500,000 1,600,000	296,600,000 1,900,000	1,150,000 1,400,000		
United (States)	305,000 47,500	Na.	Na.	7,707,000 134,500	1	76,000,000 2,970,000

Heavy figures give population. Lighter figures give area (in square miles).

The tropical world has been appropriated, and this country has a burden of tropical population six times greater than the other three combined. A few comparatively small districts remain either independent, or as yet unexplored, as Abyssinia and parts of Polynesia.

THE DOUBLE BURDEN OF THE WHITE MAN.

It is no light burden for the white man to administer this vast trust. It is, indeed, a heavy task, but the responsibility of Empire has been the making of the race. In dealing with subject nations there are only two problems of the first rank—order and health. The first of these may be said to be a speciality of the Anglo-Saxon. Scarlet sins may be laid at his door—there are many pages in the story of his world-exodus which we would fain blot out; too often he has gone forth in the spirit of the Old Testament crying "The sword of the Lord and Gideon." But heap in one pan of the balance all the grievous tragedies of America and of Australasia, the wholesale destruction of native races, all the bloodshed of India, and the calamities of South Africa, and in the other pan put just the one little word "order," which has everywhere followed the flag, and it alone makes the other kick the beam. Every-where this has been the special and most successful feature of British rule. We are entering upon a phase in which the natural results of this stable government upon the subject races are shown. Just as at home the fate of the rich is indissolubly bound up with that of the poor, so in the dependencies the fate of the strong and the weak cannot be dissevered; and whether he will bear or whether he will forbear, the brother's keeper doctrine of the strong, helpful brother must be preached to the white man. The responsi-bility is upon the nation to maintain certain standards which our civilisation recognises as indispensable on the supposition that our Western ideas are right; but we have to meet the fact that the ways of the natives are not our ways, nor their thoughts our thoughts; and yet we place them in such a position that sooner or later they become joint heritors with us of certain civil and social traditions and aspirations. It is in India and the Philippines that the political problem looms large, but no matter how large or how formidable it must not be allowed to interfere with the great primary function of the Anglo-Saxon as a policeman. There may be a doubt as to the grafting of our manners, and still greater doubt as to the possibility of inculcating our morals; a doubt also as to the wisdom of trying everywhere to force upon them our religion; but you will, I think, agree that the second great function of the nation is to give to the inhabitants of the dependencies, Europeans or natives, good health —a freedom from plague, pestilence, and famine. And this brings me to the main subject of my address, the control of the tropics by sanitation.

THE NEW CRUSADE.

When the historian gets far enough away from the nineteenth century to see it as a whole, perhaps one feature above all others will attract his attention, since amid all the movements of that wonderful period it has been most directly

U

beneficent to the race. Political, social, religious, intellectual revolutions will demand his comments, but if I am not greatly mistaken the movement upon which he will dwell longest will be the introduction of modern sanitation. It is not possible to ascribe the credit of this to any one man or group of men in any country. The movement arose with the recognition of the true nature of the large division of what we call the infectious diseases, which are responsible for more than one half of the deaths in the community. This country may claim the merit of having first carried into practical effect sanitary laws, which have resulted in a steadily diminishing mortality from this class. The cholera epidemic in the "fifties" did a great deal to arouse public opinion, and that remarkable group of men, comprising Chadwick, Budd, Murchison, Simon, Acland, Buchanan, Russell, and B. W. Richardson, and among laymen Charles Kingsley, put practical sanitation on a scientific basis. They had grasped the conception that the battle had to be fought against a living contagion, which found in poverty, filth, and wretched homes the conditions for its existence; and an immense impetus was given when in rapid succession, in the last third of the century, the germs of a large number of the most serious of epidemic diseases were discovered. The sum total has been the abolition of many infections, such as typhus fever; an extraordinary reduction in others, as in typhoid; the almost complete abolition of postoperative sepsis through Lister's work; and the perfecting of a sanitary organisation which gives confidence to the public and prevents commercial panics. Think of the shudder that would have passed over this country 30 years ago at the announcement of an outbreak of cholera in Rotterdam, yet in August last the presence of ten cases in that city was simply commented upon, but none felt the slightest anxiety. Altogether we may say that the home defences are in a fairly satisfactory condition, but there remain the complete victory over typhoid fever, the progressive reduction in the mortality from tuberculosis, and the limitation of the still very fatal diseases of childhood, and we have not arranged yet even a truce with that subtle and very progressive foe, cancer.

This flowery and flattering picture is true of the little island which forms the centre, and it is true, fortunately, to a great extent of the Confederated States, but when we take a glance at the empire at large, at the huge area which we see represented on the map, we find a totally different state of affairs. Out of the total population 60,000,000 perhaps live under good and constantly improving sanitary conditions, but of the vast dependencies with their teeming millions there is a very different story to be told. With an awakening of an interest in the Tropics men have learned to recognise the primary importance of good health and the possibility of mitigating conditions which favour the persistence of widespread and destructive epidemics. Of tropical diseases of the first importance may be mentioned malaria, plague, cholera, yellow fever, dysentery, beri-beri, and relapsing fever, and certain parasitic disorders as ankylostomiasis. They vary in their prevalence in different localities, but together they make the Tropics' great enemies. It is interesting to note that of all but one we know the germs, the conditions of their growth, and in nearly all the mode of propagation. Quietly but surely this great work has been accomplished by a group of patient investigators, many of whom have sacrificed health and life in their endeavours. Let us pause a moment to pay a tribute of gratitude to these saviours of humanity who have made the new mission possible—to Pasteur, to Koch, to Laveran, to Reed and his fellows, to Ross, Manson, and Bruce. And let us not forget that they built upon foundations laid by thousands of silent workers whose names we have forgotten. A great literature exists in the contributions published during the past century by the members of the medical department of the old East India Company service and of the army in both the East and West Indies. I should like to awaken in your memories the names of Lind, Annesley, Moorehead, Pringle, Ballingall, MacGregor, Hillary, Waring, Cheevers, Parkes, Malcolmson, and Fayrer. Many did work of the very first quality with very little recognition at home or abroad. I sometimes think of the pathetic letters received from that splendid investigator Vandyke Carter of Bombay, the first in India to confirm the modern studies upon malaria in the early days when we were both working at the subject, how he spoke of his isolation, the difficulties under which he | tion of one of the world's greatest plagues, which has cost

struggled, the impossibility of arousing the apathy of the officials, and the scepticism as to the utility of science.

No one has expressed more deeply this sentiment of lonely isolation in the Tropics than Ronald Ross in his poem In Roile :-

"Long, long the barren years; Long, long, O Go 1, hast Thou Appointed for our tears This term of exile."

Few have been able to sing with him the psean of victory when he discovered the mode of dissemination of malaria through the mosquito-

> Seeking His secret deeds With tears and toiling breath, I find thy cunning seeds, O million-murdering death."

And the pathway of victory is strewn with the bodies of men who have cheerfully laid down their lives in the search for the secrets of these deadly diseases—true martyrs of science, such as were Myers, my friend and former assistant, Lazear (both of whom died from yellow fever), Dutton, and young Manson. Of them may fitly be sung in words from the noblest of all American poems, that in which Lowell pays a tribute to the young Harvard men who fell in the war of secession :-

"Many in sad faith sought for her,
Many with crossed hands sighed for her;
But these, our brothers, fought for her,
At life's dear peril wrought for her,
So loved her that they died for her."

As a result of 25 years' work we have an extraordinary volume of knowledge concerning the causes of most of the tropical diseases and the nature of the measures required tropical diseases and the nature of the measures required for their prevention. And yet when one considers the existing conditions it is safe to say that our task has scarcely begun. When we read in THE LANCET of Oct. 23rd that during the last four months of 1908 400,000 deaths from fever were reported in the property and that it is estimated that a fourth of the Punjab, and that it is estimated that a fourth of the total population of the province suffered from malaria, one realises the truth of such a statement. And yet the situation is one full of encouragement, particularly in connexion with the practical prevention of insect-borne diseases For centuries there has been a popular belief in the transmission of disease through mosquitoes and flies, and in the middle of the nineteenth century that remarkable clinician and anthropologist, Nott of Mobile, suggested the association between the mosquito and yellow fever and malaria. A more scientific presentation of the question was made by the French physician Beauperthuy, an enthusiastic student of the epidemics in the Spanish Main. But the first clear demonstration of a mosquito-borne disease was made by Manson in the case of filariasis. The whole story is told in a fascinating way in Sir Rubert Boyce's just issued work, "The Mosquito or Man: the Conquest of the Tropical World." The discovery by Laveran in 1880 of the parasite of malaria, the demonstration by Ross in 1897 of the part played by the mosquito in its transmission, have a greater significance for a greater number of persons than any single observations ever made in connexion with disease. Then followed in 1900 the demonstration by the American Army Commissioners, Reed, Carroll, Agramonte, and Lazear of the transmission of yellow fever by the mosquito.

Many scientific discoveries have afforded brilliant illustrations of the course to be followed in a modern research; but one is at a loss to know which to admire most, the extraordinary accuracy and precision of the experiments, or the heroism of the men, officers and rank-and-file, who carried them out, all the time playing with death and some of them paying the penalty. The conditions were favourable to the demonstration on a large scale of the practical value of the discovery. It was a fortunate thing that the head of the American occupation of Cuba was General Leonard Wood, himself a well-trained physician, and deeply interested in problems of sanitation. Backed by the military arm it took Dr. Gorgas and his colleagues nine months to clear Havana, which had been for centuries a stronghold of the disease. With the exception of a slight outbreak after the withdrawal of the American troops the city has remained free from yellow fever. What is even more important, in the great centres in South America, particularly in Rio, similar measures have been carried out with signal success; indeed, we may say that the possibility is in sight of the exterminamillions of lives and has at intervals interrupted the commerce of half a continent.

I mentioned yellow fever first because its history illustrates the importance of effective organisation. It has been an added merit to Dr. Ross's great merit that, like the fiery Peter of old, he has preached a ceaseless crusade in favour of organised effort against malaria. Everyone knows that the control of the Tropics is bound up with this disease, and it is a problem the practical solution of which will tax to the uttermost the organising capacity of the Anglo-Saxon. A singularly happy combination of circumstances has demonstrated on a large scale the efficiency of modern sanitary measures in one of the world's greatest death-traps.

THE STORY OF THE PANAMA CANAL.

In a general way the story of the Panama Canal is well known, but as I do not think an up-to-date version has ever been presented to the British public I propose to tell you in a few words a marvellous history of sanitary organisation. The narrow Isthmus, separating the two great oceans and joining the two great continents, has borne for four centuries an evil repute as the white man's grave. Silent upon the peak of Darien stout Cortez with eagle eye gazed at the Pacific. As early as 1520 Saavedra proposed to cut a canal through the Isthmus. There the first city was founded in the new world which still bears the name Panama. Spaniards, English, and French fought along its coasts; to it the founder of the Bank of England took his ill-fated colony; Raleigh, Drake, Morgan the buccaneer, and scores of adventurers seeking gold, found in fever an enemy stronger than the Spaniard. For years the plague-stricken Isthmus was abandoned to the negroes and the half breeds, until in 1849, stimulated by the gold fever of California, a railway was begun by the American engineers, Totten and Trautwine, and completed in 1855, a railway every tie of which cost the life of a man.

The dream of navigators and practical engineers was taken in hand by Ferdinand de Lesseps in January, 1881. For 23 weary years the French company struggled against financial difficulties at home and insuperable sanitary obstacles on the Isthmus. Little did the 19 Frenchmen, who reached Panama in January, 1881, think that the secret of success lay 7000 miles away with a young countryman of theirs, an army surgeon in Algiers called Laveran, unknown, solitary, unrecognised, who was quietly studying malaria in a military hospital in Algiers, doing work which alone could make possible the completion of their plans.

From the outset the chief obstacle proved to be the fevers. It is a sad record. Within seven months from beginning work the mortality had risen to the rate of 119 per 1000 for the month. As the number of employees rose, so in a certain measure did the death-rate, which reached the maximum in the month of September, 1885, in the appalling figures of 176.97 deaths per 1000. This would appear to be about the maximum death-rate of the British army in the West Indies in the nineteenth century. The average in Jamaica for the 20 years ending 1836 was 101 per 1000. At several stations it reached as high as 178 per 1000. But this is nothing to some of the seventeenth century records, which show that a regiment of 800 lost two-thirds of its strength in a fortnight. The maximum number of employees was in 1887 and 1888 from 15,000 to nearly 18.000. maximum mortality in these two years was 72.48 per 1000. Then for a period of eight or ten years the work lagged, and the total number of men employed annually was for many years under 1000; a large proportion coloured and the whites chiefly immunes. Only once in these years did the mortality rise above 133 per 1000, which was in the month of January, 1903, and this seems largely to have been due to an epidemic of small-pox. Yellow fever, malaria, and dysentery were responsible for the large proportion of deaths. From 1890 yellow fever practically disappeared, with the exception of a small epidemic in 1897. During the French occupation 6283 of the employees died in hospital, thousands died along the course of the canal; many thousands were damaged permanently in health, or died after their return to their homes. In Philadelphia in 1888 I had a telegram from a contractor asking what accommodation could be given in the hospitals for two ship-loads of workmen returning from the canal, the great

majority of them ill with malaria and dysentery. mortality had been very high as yellow fever had been raging. One of the ships came to Philadelphia and I do not remember ever to have seen a more appalling sight when these victims of chronic dysentery and malaria were landed; many were anæmic, others worn to the bone, and not a man of them had escaped serious damage. Not 50 per cent. of those who had gone out returned, and a very large proportion of those who landed in New York and Philadelphia died subsequently.

When in 1904 the United States undertook to complete the canal everyone felt that the success or failure was largely a matter of sanitary control. The necessary knowledge existed, but under the circumstances could it be made effective? Many were doubtful. Fortunately, there was at the time in the United States army a man who had already served an apprenticeship in Cuba, and to whom more than to anyone else was due the disappearance of yellow fever from that island. I know that to a man the profession in the United States felt that could Dr. Gorgas be given full control of the sanitary affairs of the Panama zone the health problem, which meant the canal problem, could be solved. There was at first a serious difficulty relating to the necessary administrative control by a sanitary officer. In an interview which Dr. Welch and I had with President Roosevelt he keenly felt this difficulty and promised to do his best to have it rectified. It is an open secret that at first, as was perhaps only natural, matters did not go very smoothly, and it took a year or more to get properly organised. Yellow fever recurred on the Isthmus in 1904 and in the early part of 1905. It was really a colossal task in itself to undertake the cleaning of the city of Panama, which had been for centuries a pest-house, and the mortality of which, even after the American occupation, reached one month as high as 71 per 1000 living. There have been a great many brilliant illustrations of the practical application of science in preserving the health of a community and in saving life, but it is safe to say, considering the circumstances, the past history, and the extraordinary difficulties to be overcome, the work accomplished by the Isthmian Canal Commission is unique. 1905 largely dealt with organisation, yellow fever was got rid of, and at the end of the year the total mortality among the whites had fallen to 8 per 1000, but among the blacks it was still high, 44. For three years with a progressively increasing staff which had risen to above 40,000, of whom more than 12,000 were white, the death-rate progressively

Of the six important tropical diseases, plague, which reached the Isthmus one year, was quickly held in check. Yellow fever, the most dreaded of them all, has not been present for three years. Beri-beri, which in 1906 caused 68 deaths, in 1908 caused only 38. The hook-worm disease, ankylostomiasis, has steadily decreased. From the very outset malaria has been taken as the measure of sanitary efficiency. Throughout the French occupation it was the chief enemy to be considered, not only because of its fatality, but on account of the prolonged incapacity following infection. In 1906 out of every 1000 employees there were admitted to the hospital, from malaria 821; in 1907, 424; and in 1908, 282. The mortality from the disease has fallen from 233 in 1906 to 154 in 1907, and 73 in 1908; that is to say, with a force more than a third larger in 1908 there were only a third the number of deaths that occurred in 1906. Dysentery, next to malaria the most serious of the tropical diseases in the zone, caused 69 deaths in 1906; 48 in 1907; and in 1908 with nearly 44,000 only 16 deaths. But it is when the general figures are taken that we see the extraordinary reduction that has taken place. Out of every 1000 engaged in 1908 only a third of the number died that died in 1906, and half the number that died in 1907.

The death-rate among white males has fallen to 3.84 per 1000. The rate among the 2674 American women and children connected with the Commission was only 9.72 per 1000. But by far the most gratifying reduction is among the blacks, the rate of which had fallen to the surpri-ingly low figure in 1908 of 12 76 per 1000; in 1906 it was 47 per 1000. A remarkable result is that in 1908 the combined tropical diseases—malaria, dysentery, and beri-beri—killed fewer than the two great killing diseases of the temperate zone, pneumonia and tuberculosis-127 in one group and 137 in the other. The whole story is expressed in two words.

¹ Maunsell, Jamaica branch of the British Medical Association, Proceedings, Year 3, No. 12.

effective organisation, and the special value of this experiment in sanitation is that it has been made, and made successfully, in one of the great plague spots of the world.

In Italy, in India, in many parts of Africa, and in the United States the anti-malarial campaigns are being pushed with the same vigour and success, but time will not permit me to dwell upon any of these or upon the brilliant success which has followed the work of Bruce and his colleagues in clearing Malta of Malta fever, but I must stop to refer briefly to certain dark shadows in the picture of tropical medicine. Within ten years the investigations in Africa have shown the wide prevalence of formidable diseases of animal and man, unknown or previously but imperfectly known. The knowledge of the group of diseases caused by the trypanosomes has added terror to tropical life. The dreaded sleeping sickness which now extends over some million of square miles is one of the serious problems of life in Africa. A vigorous plan of campaign has been instituted, and already in Uganda, as the Governor's report shows, there is a steady diminution, and no whites have been attacked since 1906. The public will find in Boyce's book the whole story of the relation of tropical diseases to flies and insects, and this most timely contribution should help to call attention to the medical problems of the tropics and the supreme interest to the nation of these new maladies. And there is another dark spot in our story.

THE RECRUDESCENCE OF PLAGUE.

Certain epidemic diseases are very much like the fabled "Hydra," from which so soon as one head was cut off another sprang up to take its place, or what is just as bad grew Even the eternal watchfulness which safety demands is not of any avail against the workings of nature when we do not understand her laws, and when we are face to face with certain mysterious phenomena, the sweep of whose orbit we have not yet measured. Geologists tell us of epochs when there must have been a wholesale destruction of certain types, possibly by disease. More than once within historic days it must have seemed as if the very existence of the race was threatened, so vast and overpowering had been an epidemic invasion. No disease had so shaken the foundations of human society as the plague, which in the second century and again in the thirteenth has shown a capacity for wholesale destruction not shared by any other. In reading the Abbé Gasquet's picture of the effects of the great pandemic of the thirteenth century one gets the impression of the loosening of an irresistible cosmic force which swept like a tornado over the earth, leaving it desolate and almost uninhabited. We have traced the orbits of the planets, and the advent again of Halley's comet shows us how fully we understand the stars in their courses, but these are mechanical things, the laws of which are plain and legible in comparison with the many and as yet insoluble problems of life. One of these relates particularly to the extraordinary reappearance or recrudescence of certain epidemic diseases. 20 years ago when one spoke of the plague memories were recalled of the history of Athens in the days of Pericles, of Rome in the days of Marcus Aurelius, of the great pandemics of the Middle Ages, and then of the dwindling smaller epidemics of the sixteenth, seventeenth, and eighteenth centuries. But to the profession and to the world at large the plague was a closed book. A few knew that it lingered in certain centres, but none dreamed that it would again burst like the comet into our orbit. There was a certain fitness that it should have started on a world mission of destruction at Hong-Kong, the port which boasts the largest and most world-wide tonnage. When one considers the dynamic energy of the plague, its powers of resistance, its terrible killing capacity, exceeding all known vital forces, who can doubt that had its advent been in the middle instead of at the end of the last century civilisation might have had to face again the prospect of destruction. With slow delibera-tion since in 1894 it started in Hong-Kong it has reached 52 countries in every district of the world (J. M. Eager).

The outbreak in India, which began in 1896, has shown that under suitable conditions the disease has lost none of its old malignancy. With the exception of a slight decrease in the years 1900 and 1906, there has been a constant annual increase in the number of deaths, the total amounting now to between 6.000,000 and 7,000,000. On the whole, in other

prevalence during 15 years the total mortality cannot be said to be excessive. The two serious features relate to the difficulty of enforcing successful measures in India, and the extraordinary tenacity it has displayed in spite of the most vigorous measures for its total suppression. It is not without significance that at Glasgow, where there were small outbreaks in 1900 and 1901, two cases occurred in 1907 which could not be traced directly to shipping. Lucretius says, in describing the great plague in Athens: "Appalled and doubtful mused the healing Art"; but we have made a great step in our knowledge of the means of its dissemination, and though we may well be appalled at the virulence of the disease in India, we have no cause to doubt the efficacy of the machinery which is keeping it in check all over the world. As an offset to the dark picture, India is the very country above all others in which the health of the European has progressively improved. The army statistics show an extraordinary reduction in the death-rate from typhoid fever, dysentery, and from malaria. Lord Kitchener remarked the other day that the improvement of the English troops in India in the past 10 years was equivalent to adding 2000 men to the strength of the army.

PLAN OF CAMPAIGN.

I have indicated briefly to you the pressing necessity to take up the heavy burden of securing health in the tropics. To make our knowledge effective, to make it as effective as Dr. Gorgas has done at the Isthmus of Panama, as Ross has done at Ismailia, is the problem which to day confronts us. Enough has already been accomplished to indicate a successful plan of campaign. Two things are necessary. First, organised centres from which the work may proceed; a model of this sort is the "Sleeping Sickness" Bureau under the auspices of the Royal Society. The work which it has done and which is under progress shows the value of central organisation. Similar central bodies have already dealt with plague and malaria, but these organisations should be placed on a permanent basis and unified in some way under a central Tropical Institute, the different departments of which would be in touch with its workers all over the

How fascinating to stand at the window of the Norddeutscher Lloyd's office in Charing Cross and see the chart of the position of every ship of their great fleet as it plies the seas of commerce, and one turns away with a tribute of admiration to enterprise and organisation. Given two not unattainable features, an Imperial Tropical Institute and strong affiliated schools, the health side of the burden of Empire might be undertaken with a staff of highly trained workers who could be sent hither and thither, wherever there was a disease to be investigated or a pest-hole to be cleared up. map would show one hundred or more expeditions planted in India, Africa, and America, all like the Lloyd's ships, a testimony to organisation and enterprise. And this is no vain dream. By far the most useful work in British medicine during the past 20 years has been the result of just these carefully planned expeditions, sent out, partly by the liberality of the citizens of Liverpool, particularly Sir Alfred Jones, and partly as commissions by the Government and by the Royal Society. Not only have they added enormously to our knowledge of tropical diseases, particularly of plague, Malta fever, and sleeping sickness, but they have demonstrated the necessity of working at these diseases in the regions of their prevalence. It is not too much to say that the reports of the Liverpool School and of the Royal Society and the Government commissions are among the most valuable contributions made of late in this country to scientific medicine. More than this, there has in consequence taken place an extraordinary awakening of the profession to the importance of tropical disease, societies for its study have been organised in different countries, an International Society has been formed, special journals founded, at large seaports hospital wards devoted entirely to tropical diseases have been opened, and lastly schools for the study of tropical diseases have been organised. And here I come to one of the great factors in securing proper sanitation in the tropics-suitable provision for the training of workers. The country may feel a just pride in the schools which have been started in the two great seaports of the nation. In the hands of Ronald Ross and Rubert Boyce the Liverpool school, founded 10 years ago by countries it has been held in check, and for so pandemic a Sir Alfred Jones, has had a career of exceptional vigour.

Ħ

Zį

Backed by the citizens, and particularly by those princely souls Sir Alfred Jones and Mr. William Johnston, and with the cooperation of the University of Liverpool, it has drawn students and investigators from all parts of the Empire and from foreign countries. As an indication of its vitality I may mention that the school has already despatched 21 research expeditions to the tropics. And I am told that the entire "plant" of the school and the cost of the expeditions have been less than £75,000, a very modest sum considering the results. Started just 10 years ago by the wise support of Mr. Joseph Chamberlain, who will always be gratefully remembered as the statesman who taught us to think tropically, this school has had the great advantage of the guidance and the prestige of the name of Sir Patrick Manson, the dean of all students of tropical medicine. To him more than to any one man we owe the strong position occupied by the subject to-day in Great Britain. You have been singularly fortunate in securing a staff of teachers well known for their researches in tropical medicine, such as Sandwith, Simpson, Duncan, Cantlie, and Sambon, a director of such unusual experience as Daniels, and such well-recognised authorities as Leiper and Wenyon on helminthology and parasitology. In the heart of the Empire, in its richest and largest city, to which all the world pays tribute, one naturally expects a foundation commensurate with its advantages and responsibilities. With the aid of the Government and a few liberal friends a good start has been made and the school has taken a strong position among the educa-tional institutions of the country. In the short time of its existence, it has trained nearly 1000 men for work in the colonies and dependencies, it has fostered original research in tropical diseases, and it has been an important centre for the diffusion of scientific knowledge. Need I dwell upon its peculiarly fortunate situation in the very midst of the commerce of the world, where sailors from every region congregate, bringing with them the diseases peculiar to their homes. The possibilities exist for the greatest of all schools of tropical medicine if London will but rise to the occasion. Liberal and encouraging at the outset, the Government has taken the usual course and has thrown upon the public the chief responsibility for its support. After reading a statement of the finances of the school furnished by the secretary, I am astonished that so much good work has been done with so meagre an endowment. Only the self-sacrificing devotion of the staff has enabled the school to achieve its marked success. I am sorry to have to say that neither the City of London as a corporation, nor its rich guilds, nor its citizens have contributed to the cause as might have been expected. The total expenditure on the school has been less than £40,000, a sum not more than sufficient to endow one department. As we all know, the extraordinary demands upon London are met in a way that makes it the centre for all beneficent enterprises. For church missions alone millions are contributed annually. It is not too much to ask for rich endowments for the missions of science.

I have tried to indicate the position which the new crusade occupies in the work of the nation, a work coördinate with, and almost of the same importance as, that of maintaining order. We cannot expect much more from the Government, which throws the onus of endowment upon private hands, but it makes the struggle hard when we come into competition with the Government-supported institutions of other countries. London, which should be the centre of the Empire, not alone commercially but in every relation, cannot be said to have kept pace in science with modern demands, and it has never realised its imperial position for post-graduate study. It is not a good thing for the Empire to find that so many of our young men who come from overseas for work slip away to the continent where they find conditions more favourable and better organised. It is not the sort of impression which one would like to have taken away from the Imperial capital.

This great question of tropical sanitation, in which we have only made a start, is bound to loom in larger and larger importance. Of the nations, England has the heaviest responsibility, as the figures I have quoted show, but she has the advantage of the first start and of strongly ingrained national ideas on the value of health. not too late to seize the opportunity. The United States, Germany, France, Holland, and Japan are in the field. Now is the time for new enterprise and a more complete organisation. That the Government is friendly and begins to realise the importance of the work is evident in the

appointment of an entomological commission; but this is a vast and complicated problem which needs an organised effort on the lines I have indicated. An Imperial Institute would represent the general staff of an army of sanitation, the expeditionary forces of which could concentrate at any place and could be used for investigation, education, and supervision. Each unit would represent the staff of one of Dr. Gorgas's 17 divisions of the Panama Canal Zone and would take hold of an insanitary district and leave it pest free. Affiliated and ancillary would be the two schools which would serve as training colleges for investigators and sanitary administrators. Take, for example, this school. If I were Minister for tropical dependencies and a friend of a Chancellor of the Exchequer with a big balance, I would first establish six professorships, two of tropical medicine with a hospital of 200 beds, a good clinical laboratory, and a system of graded associates and assistants; a professor of pathology with a separate institute—and the model of the new one at Leipsic would be thought good enough; a professor of protozoology; a professor of helminthology; a professor of entomology-all of whom would have earte blanche for their latoratories, museums, and libraries. I would establish subsidiary schools in the tropics, in West Africa, Uganda, and India which would serve as centres for the mission work in those countries. By no means a visionary scheme, and well within the possibility of achievement, it would not demand an endowment of more than a couple of millions. Once get the intelligent business men to take up this as a business scheme in the interests of the whole Empire, and they will not, as they never have in the past, shirk their duty, but in slow and steady streams of a few thousands now and then, in big rushes, let us hope, of a hundred thousand now and again, the necessary amount will be made up.

Is it likely that the white man can ever thrive in the tropics except as a sort of exotic, as he is at present in the West and East Indies? As the nations of the north and south increase and multiply, doubling every century, will he find an outlet by settlement in the tropics, or will he simply use them as Rome did Egypt, as a granary? It cannot be said that so far the European has been a success as a settler in the tropics, since no white colony has ever prospered below 30 degrees of northern latitude, but has he ever had a chance? In contact with brown and black races, which have become inured to heat, tolerant of parasites, and more or less immune to the worst of the tropical diseases, he has so far never had an opportunity to show of what he might be capable when placed in really sanitary surroundings. The 8000 whites now at the Isthmus work eight hours a day in the burning sun, and they with their wives and children thrive and enjoy a health quite as good as dwellers in any town in the United States. Heretofore man has never met nature on equal terms; now science has taught him how to be master, but the knowledge is so new and so recently made effective that we have not the data from which to make a clear judgment. How far the introduction of tropical diseases has accounted for the decadence of Greece has been discussed by W. H. S. Jones and Ronald Ross, who seem to have made out a good case, but given a white race living in the tropics for two generations, and free from malaria and parasitic anæmia, would it show the hardy vigour at present the characteristic of the Anglo-Saxon? Time alone will tell. Personally I doubt it. Man is a lazy animal, and the best thing that ever happened in his history was when Adam's wife ate the apple and they both were turned out of a tropical Eden to ean their bread by the sweat of their brows. As Sir Charles Dilke has remarked, the banana is the curse of the tropics, and when have ever "the blossom-fed Lotophagi" done anything for the race? The most successful attempt has been in the English West Indies, but commercial conditions have been adverse, and to-day the negro may be said to possess the islands where the white man lives it is true, but hardly thrives. No, it has been found in the past, and it will be found in the future, that the men of mettle, the men who have made the world their Odyssey, have been reared in Ithaca's rugged Isle "of hardy youths a nurse of name." is good for man to have the "rebuff that turns earth's smoothness rough." and this is not what he gets amid the fascination and fertility of the tropics, which, as Homer says, breeds-

> Of proud-lived loiterers that never sow Nor put a plant in earth, nor use But trust in God for all things."

When Isaiah was discussing the burden of Babylon, the burden of Tyre, and the burden of Egypt, I wonder what he would have said could his prophetic eye have glanced at the map on which is depicted the burden of the British Empire. Surely no nation in history has ever had such a load of responsibility. But fit as it has been in the past it will ever be fit so long as salus populi remains suprema lex. It only behoves us to see that we are well equipped for the second great task—the task of the future, to give to the teeming millions of our dependencies that greatest of all blessings in life, good health.

A Necture

AN IMPROVED METHOD OF REMOVING THE TESTICLE AND SPERMATIC CORD FOR MALIGNANT DISEASE.

Delivered at the Middlesex Hospital

By JOHN BLAND-SUTTON, F.R.C.S. Eng., SURGEON TO THE HOSPITAL

GENTLEMEN, -Tradition plays an unconscious part in the acts of the most unconventional surgeon. This is the only explanation I can offer concerning the universal practice among surgeons when performing the ancient operation of castration for malignant disease of the testis, in allowing their efforts to be limited by the internal abdominal ring.

The immediate risks of orchidectomy for malignant disease

under modern conditions are trifling. The remote results are most discouraging, for within a few months, in the majority of instances, the disease returns in the stump of the spermatic cord (recurrence); or the lumbar lymph glands become infected with cancer and form huge masses in the abdomen (direct lymphatic infection); or secondary nodules appear in various parts of the body (dissemination). It is undeniable that the modern method of extirpating the primary growth, the associated lymphatics, and the lymphglands (or nodes) in dealing with cancerous organs has greatly improved the remote results of operations designed for the relief of cancer. This is manifest in the case of the breast, the lips, and the labia. As far as I know no one has attempted to apply this method in the operative treatment of malignant disease of the testicle. I determined, when a suitable case came under my care, to remove the testis, the spermatic cord, with its arteries, veins, and lymphatics, and the associated lymph-glands which lie on the inferior vena

In September, 1909, a man, 31 years of age, consulted me on account of an enlarged right testicle. The increased size of the organ, its weight, and non-translucency indicated clearly that the organ was attacked by malignant disease. The enlargement was obvious in February, and had been progressive. The left testis was retained in the inguinal canal. The patient readily submitted to any measures which promised him relief. After due preparation the following operation was performed at the Middlesex Hospital.

The scrotum was freely incised and the right testis was exposed. I then introduced the scalpel into the testis to satisfy myself that the enlargement depended on a growth. The testis was freed from its investments and the spermatic cord was isolated as far as the internal abdominal ring. After much of the loose scrotal skin had been removed, the bleeding vessels were ligatured with fine silk, and the testicle was enveloped in a fold of sterilised gauze. Up to this point the operation had been conducted with hands enclosed in sterilised rubber gloves; these were removed and the hands were carefully washed for the second stage.

This consisted in making a free incision of the right abdominal wall in the line of the linea semilunaris from the costal arch to the opening in the inguinal canal. The incision divided all the structures of the anterior abdominal wall down to the peritoneum. peritoneum. Gentle tension on the testicle soon showed the position of the spermatic vessels lying in the loose areolar subperitoneal tissue. In order to isolate them they were surrounded by a thin silk ligature just before their

The vas deferens and its termination in the vena cava. artery were ligatured and divided at the brim of the pelvis. I then detected a hernial sac lying in relation with the spermatic cord; its neck was encircled with silk and the pouch was removed with the cord and testicle. At this stage the retroperitoneal tissues of the right lumbar region were well exposed and this enabled me to examine the parts about the aorta and search for enlarged lymph-glands. I found one on a level with the third lumbar vertebra, lying on the anterior face of the vena cava; although as big as a haricot bean it shelled out easily. A very careful search was made for other lymph-glands but without success. In spite of the large area of tissue opened up there was very little loss of blood, and the only vessels, apart from the spermatics, which required to be ligatured were those divided in the scrotum and in the abdominal wall. The abdominal incision was closed by means of interrupted silk sutures, and the cut edges of the scrotum were brought together by sutures of thin silk. It was thought to be prudent to insert a narrow rubber tube into the depths of this extensive wound for 24 hours. The wound was dressed with sterilised gauze and Gamgee tissue, held in position by a many-tail bandage, reinforced in the inguinal region by a spica bandage. Afebrile healing followed, with a rapid convalescence. The patient left the hospital on the seventeenth day after the operation.

The parts removed were hardened in equal parts of methylated spirit and water. The enlarged lymph-gland was prepared for microscopical examination by Mr. Somerville Hastings, and we were surprised on looking at the sections to find that they contained cystic spaces lined in some sections with columnar or sub-columnar epithelium. In a few it was stratified. This, of course, indicated the nature of the primary growth. Ten days after the operation I divided the testis and found a cystic tumour occupying the space between the epididymis and the body of the testis. The secreting tissue, compressed into a thin stratum, formed a

strap over the upper pole of the tumour.

On microscopical examination the tumour presented the usual characters of its class, inasmuch as it consists of a complex arrangement of intercommunicating tubules embedded in a richly cellular connective tissue stroma, presenting, here and there, cylindrical knobs of hyalin cartilage. In some parts of the stroma, strands of tissue very like unstriped muscle tissue were seen. The tubules were lined with epithelium, which in some of them was stratified, and in others columnar in shape. When the structure and epithelial lining of the tubules in the primary tumour were compared with the cysts in the lymph-gland removed from the loin the identity was complete. This is sufficient proof of the malignancy of the tumour which, in its microscopic, as well as in its general, features, might easily be regarded as an innocent species. I have devoted much time during the last quarter of a century to the study of the secondary deposits of malignant disease, but no better example of the detailed reproduction of the structural features of a primary tumour has come under my observation than the cystic growths which we found in the lymph-gland of the man the subject of these observations.

CYSTIC DISEASE OF THE TESTIS.

Our knowledge of these remarkable tumours was greatly increased in 1853 by Curling; he named this condition "general cystic disease" of the testis, and pointed out two of their most important features namely, the frequent presence of hyalin cartilage in them and the fact that such tumours are situated between the epididymis and the testisproper. As the tumour increases in size it squeezes the secreting tissue of the gland and flattens it out till it forms a thin stratum over its upper pole. (Fig. 1.) This led Curling to believe that such cystic tumours arose in the rete testis; his observations have borne fruit and have led several investigators to take an interest in them. There are three kinds, or species, of tumour which arise in the tissues between the epididymis and body of the testis. In their type forms they are quite distinct and receive specific names : (a) adenoma testis; (b) cystic disease of the testis; and (c) dermoid or teratoma of the testis. In their intermediate forms they run one into the other and examples occasionally come to hand in which the characters of all three are

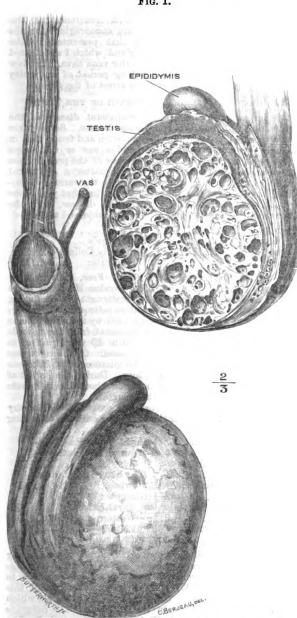

The adenoma testis in its typical form is a solid tumour;

it is composed of tubules formed of epithelium with a narrow central lumen. The epithelium in the specimens I have examined resembles the epithelial cylinders which are often found in the renal sarcomata of infants, but in testicular adenomata the epithelial cylinders often lie juxta-posed without the intervention of connective tissue. Tracts posed without the intervention of connective tissue. of cartilage are sometimes present, whilst here and there in some apparently completely solid tumours, cysts due to the dilatation of the tubules, are seen in the sections.

some notion of its rarity it may be mentioned that specimens of the adenomatous and the cystic species exist in all the pathological museums attached to the medical schools of the metropolis, but there are only three specimens of testicular dermoids containing hair. There is one at the Royal College of Surgeons of England, one at St. Bartholomew's Hospital, and one at St. Mary's Hospital.

During the last 30 years four examples of testicular dermoids have been reported by Englishmen-namely,

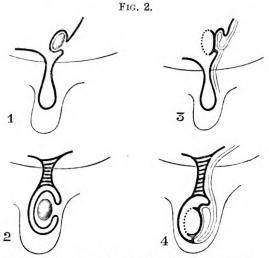

A testis with the spermatic cord and the spermatic vessels. removed by operation from a man 31 years of age. A hernial sac was removed with it. The testis is shown in section. A cystic tumour has grown between the body of the testis and its epididymis. The secreting tissue of the testis is flattened over the upper pole of the tumour.

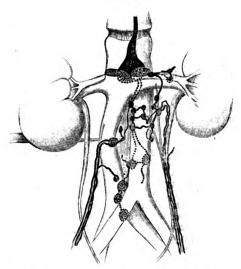

The cystic form is well illustrated by the specimen repre sented in Fig. 1. It differs from the adenomatous species in that the epithelial cylinders are dilated and the lining epithelium has become altered in shape in response to the pressure exerted by the accumulated fluid within the tubule.

The dermoid or teratomatous species is as striking in its general naked-eye features as the cystic form, for it contains hair and often teeth. It is, however, in its most developed form the rarest of all tumours of the testis. In order to give

A series of diagrams to show the old and the new view of the peritoneal relations of the testis. Diagrams 1 and 2 represent the peritoneal relations of the testis during and after its descent as usually taught. Diagrams 2 and 3 illustrate the Hoffmann-Frankl view in which the body of the testis is shown as an intraperitoneal organ (after

Fig. 3.

A diagram showing the position and relations of the lymph-glands associated with the testes. The results were obtained by means of fine injections. (After Most.)

D'Arcy Power, 1887; Jackson Clarke, 1896; Kuhne, 1908; and the writer. The sources of these testes are interesting, for Clarke's specimen was removed from a Hindu boy by Lieutenant-Colonel G. M J. Giles; my specimen was removed from a Chinese lad at Hankow by Dr. R. T. Booth; and Kuhne's specimen was obtained from a Chinese boy, aged 4 years, at Tungkau. Recently another specimen has been obtained in London which I trust will soon be described.

We have in these three species of tumour a very natural genus, Testicular teratomata. In their type forms they present clearly defined characters, but in the intermediate forms they run gradually one into the other, and the dermoid or teratomatous species contains all the structures which are found in the solid and the cystic forms. Moreover, the mode of origin of these tumours in the tissues, between epididymis and testis proper, constitutes a very striking common feature independently of the histological evidence concerning the similitude of the peculiar structures which form so much of their bulk.

Embryologists have by no means been idle, for they have investigated the nature of the tissues in the vicinity of the rete testis, and have succeeded in detecting feetal vestiges connected with it. Some interesting observations have been made by Frankl (supporting those made by Hoffmann as long ago as 1870), which show that the outer covering of the testis is similar to that of the ovary, inasmuch as it consists of involuting germ epithelium. Moreover, we have now to appreciate the fact that our notions of the relations of the testis to the peritoneum must be changed. The body of the testis is an intraperitoneal organ (Fig. 2) like the ovary; the idea that it slips behind the peritoneal fold of the funicular pouch to be invested by it must be abandoned. The epididymis is covered with peritoneum and the limit of the peritoneal investment is obvious to the naked eye, corresponding to the white line detected by Farre on the ovary.

LYMPHATICS AND LYMPH-GLANDS.

One of the most prominent clinical features of carcinoma of the testis is the rapidity and extent of the lymph-gland infection. The great size which the lymph-glands lying in the neighbourhood of the abdominal acrta and the inferior vena cava attain in some patients is truly astonishing. The lymphatics from the testis traverse the spermatic cord (they vary in number from four to six), and accompany the spermatic veins without receiving tributaries from the tissues around them. They have no communication with the lymphatics of the scrotum and this sufficiently explains the absence of enlarged glands in the groin when the testicle is cancerous, unless the tumour has implicated the skin of the scrotum.

Most made a careful study by means of fine injections of the lymphatics and lymph glands associated with the testis, and the results of his investigation are represented in Fig. 3. Here the lymph-glands and lymphatics belonging to the testes are represented in complete outlines. Those belonging to other organs and tissues are dotted. picture is a combination of two injection-preparations: the right side represents the results obtained by injecting the right testis of a newborn infant. After filling the lymph-vessels of the spermatic cord two lymph-glands were found on the inferior vena cava. The upper gland communicates with others lying in the connective tissue behind the vena cava; one of the lymph-vessels leads to the receptaculum chyli (cisterna chyli). The left side represents results obtained by injecting the spermatic lymphatics of a boy 4 years of age. Several glands appear in relation with the aorts, and two of these communicate with the cisterna by a lymphatic lying behind the great blood-vessel. A third communicated with the cisterna by a vessel running over the anterior face of the renal vein. The cisterna chyli and the thoracic duct were quickly filled with injection fluid up to its termination in the vein. On both sides lymph glands lying near the kidney and behind the aorta and the vena cava were filled by a retrograde flow of the injectionfluid. This is a matter of importance because cases occur in which malignant tumours of the testes lead to enlargement of the lymph-glands from the fifth lumbar vertebra to the root of the neck. It is the intimate association with big blood-vessels which is the chief obstacle to the surgical removal of these cancerous lymph-glands. In the case which forms the subject of this lecture the position of the enlarged lymph-gland which I removed is accurately indicated by the upper of the two lymph-glands lying on the inferior vena cava.

The fact is clearly recognised by surgeons that the infection of the abdominal lymph glands paralyses their efforts in the effective treatment of many malignant tumours of the testis. Some surgeons (including K other and Roberts) have been enterprising enough to attempt to extirpate the retroperitoneal lymph-glands when they have formed huge lumps subsequent to the removal of the testis. Such efforts have rarely been successful, but Foulerton gives the details of a case in which a man aged 28 years had his left testicle removed in India on account of a malignant growth

described as an "adeno-sarcoma." Two years later he was admitted into the Middlesex Hospital on account of a tumour in the left side of the abdomen. In March, 1895. this mass was removed by Sir Henry Morris; it consisted of enlarged encapsuled glands which contained numerous small cysts. On microscopical examination the structure of these masses resembled that presented by the "general cystic disease" of the testis we have been considering, cystic spaces lined with epithelial cells forming a conspicuous feature of the sections. This man recovered from the operation and reported himself in July, 1896. He was in a hypochondriacal condition, but a careful examination failed to disclose any evidence suggestive of a recurrence of the disease. The details of this case are encouraging, for the histological picture accords with that presented by the sections obtained from the lymph-gland which I enucleated from the anterior surface of the inferior vena cava. In view of these facts one may look for a long period of immunity for my patient, if not for a complete arrest of the disease.

FREQUENCY OF MALIGNANT DISEASE OF THE TESTIS.

It is important to realise that malignant disease of the testis is, on the whole, an uncommon disease. Some years ago I attempted to determine this question and found that in the large general hospitals in London one or two cases represented the yearly average. In view of the present case I have made an attempt to give the matter a statistical foundation by collecting the returns from the various metropolitan hospitals for the year 1907. During that year there were 12 testes removed for malignant disease, and the distribution of the cases is shown in the subjoined table:—

London		3	Guy's		1
St. Bartholomew's		2	St. George's	•••	1
Great Northern		2	University College		1
Charing Cross	•••	1	Westminster		1

At the Middlesex, Cancer, Royal Free, St. Peter's, St. Thomas's, St. Mary's, and West London Hospitals there were no cases of orchidectomy for malignant disease during 1907. These results as to the relative infrequency of malignant disease of the testis are supported by the observations of Russell Howard. This surgeon gathered from the records of the London Hospital for a period of 20 years ending in 1907 references to 65 cases of this disease. Of these, he was able to verify the diagnosis by the microscope in 57 cases and to obtain a good clinical history. During the period of 20 years in which these cases occurred about 110,000 male patients had been admitted to the hospital.

For comparison with these results I extended the inquiry to some important towns for the same year with the following

Malignant disease of the testes occurs in infants and young boys; it is happily a rare disease. Mr. Somerville Hastings obtained the returns from ten hospitals for sick children in London for the year 1907. There were no examples of this disease during that year. The names of the hospitals which furnished returns are given in the following list:—Belgrave Hospital, Queen's Hospital, East London Hospital, Evelina Hospital, Cheyne Hospital, Paddington Green Hospital, Victoria Hospital, Grosvenor Hospital, Great Ormond-street Hospital, and Royal Waterloo Hospital.

It is not my intention to obscure the theme of this lecture by an academic discussion on the vexed question of the nature of the morbid growths which arise in the testis. The results hitherto obtained by the ancient and simple method of castration (or orchidectomy) as a means of relieving men afflicted with malignant disease of the testicle are notoriously bad; it is therefore time that efforts were made to treat these conditions on the radical lines now universally practised in regard to cancer of other external organs, notably the lips, the breast, and the labia. This consists in the wide extirpation of the area primarily affected, and the complete removal

of the associated lymphatic area and lymph-glands. The details of the operation described in this lecture show that the "radical method" is applicable to the testis, and I venture to hope that other surgeons who have the opportunity of dealing with such cases will carry out this method, and keep the patients under observation for a sufficient period to enable us to gather evidence wherewith to judge of its merits.

its merits.

TYPICAL AND FRACTIONAL PNEUMONIA.

BY SIR CLIFFORD ALLBUTT, K.C.B., M.D. CANTAB., F.R.C.P. LOND., F.R S.,

REGIUS PROFESSOR OF PHYSIC IN THE UNIVERSITY OF CAMBRIDGE.

A DISEASE is a series of symptoms, normal and abnormal, recurring in a certain species or genus with fair uniformity; not with identity, for even in health no two individuals are, or ever have been, identical, but with fair uniformity. To compass this uniformity, external causes must be fairly uniform, and the structure of the individuals likewise fairly uniform; though, again, in none of these aspects is there identity. If, the specific causes being constant, the individual be of another kind, if this side of the equation be thus varied, the issue will be a different form of disease. But it is no less evident that, as between individuals of the same kind, and again between different kinds, there are infinite gradations, so in disease the gradations are also infinite.

There are in nature, then, no compartments; for our own erigencies we fabricate classifications and Nature smiles at them, going her own way. These classifications are arbitrary; they are conventional devices to meet the finite faculties of man. If, after the French manner, we make them precise, we miss the complexity of nature, we try to gather the wind in a net; if, after the "Celtic" manner, we try to embrace the infinite we are lost in the vague. So we vacillate between the lucid and the incomprehensible, between the concise, which lets slip the finer issues but makes argument hard and brilliant, and the illimitable, for which our apprehensions and our language are alike too rudimentary. In labelling diseases, then, we shall not forget that these processes observe no precincts, and recur with only fair uniformity.

In the simplest organisms disease must be simple: creature must fall ill all ways at once. As we ascend the ladder of organisation organs are segregated, taking on more and more specific though in our experience never absolutely peculiar qualities. So likewise their perturbations must become various; they must run more and more along particular lines or issues of function; though, as the organs are not absolutely specialised, but still in various degrees can supplement each other, and this again very variously in several individuals, so in the correlative paths of disease we shall see never more than a fair uniformity, but yet more and more uniformity as we ascend the ladders of organisation, as functions are more and more segregated, and as the creature in health works more and more along many differentiated lines. The idea of the diseases possible for any particular creature is then contained in the idea of its diversified paths of function, and is as simple or as complex

Again, as in aid of classification we construct for normal functions a series of types, so we do for diseases, which run along the same more or less delineated paths, and are indeed the shadows of the several functional segregations, for which also we construct Types. And the Types are as arbitrary as the Classes: they are go-carts for the infant observer. Taking

clinical experience as our guide, we call to remembrance the cases of a certain disease in our own experience, and consult the records of the experience of others concerning it. Thus we discover that, although perhaps every symptom taken singly may be found in other, probably in many other, processes, yet in those many processes they are collected in as many different degrees of density. Some very few may indeed be almost singular—"pathognomonic," as we say—but these are admittedly few; if closely scanned, perhaps elusive. Speaking generally, the contrasts of disease lie in the areas of relative density of certain symptoms which are by no means, when taken severally, peculiar to any one of them. Among a hundred cases of pneumonia, let us say, we find many in which the symptom of tubular breathing, or of dulness of percussion, is absent, yet upon the whole the frequency of either or both of them is very high; that is, if for the hundred cases we plot out these two symptoms by stars upon a chart, we shall find the density of either or of both to be very thick. In some other diseases they would prove, it is true, to show also some density, but the differentiation (the diagnosis) would then appear on a comparison of the densities of companion symptoms. Furthermore, by making a survey of a large number of cases of a certain disease thus plotted out we should be enabled, by observing, selecting, and assembling those symptoms which proved to be of considerable density, to build up a scheme of it. This, as we have admitted, would be an arbitrary process, because in the selection we should have to neglect many margins and gaps; still, on the whole by this abstraction, or paradigm, from an adequate number of records we should find it possible, as it is possible in other spheres of thought, to construct an ideal, an imaginary picture, like that of superposed photographs, of the disease under our study. This figure is the Type; and, as on conscious or unconscious reference of each subsequent case to this ideal form we note its approximation or its divergence from this, so we speak of the cases as "typical," or as "aberrant," or even as "atypical"—that is to say, lying outside any Type. These last cases which "prove the rule" are often crucial instances, and by their very deviation may point out to the vigilant observer some deeper or cross affinity previously unsuspected.

The Type is then the ideal case which never was in bed or book; like the Class it is a mental concept in each of us, one on which we agree in so far as men's various minds in that respect are in harmony. To give real existence to these concepts of class or type, to call such an abstract idea an entity—i.e., a being—is a return towards demonology. The only entity is the particular patient under observation.

Now to return to pneumonia: a mental picture or type of it has been thus manufactured by collecting from a large number of cases the relative densities of the recorded symptoms; and amongst these we find the most frequent to be ain, fever, dyspnœa, cough, a peculiar expectoration, &c. We will call the number of symptoms or features included in the type—a somewhat arbitrary number, as we have seen, for at the edges we may heritate which to take in or to discard—this number we will call n. And we may represent the constituent symptoms by the previous letters of the alphabet, by a, b, c, d, e, and so forth. But as no case accomplishes our ideal concept of the Type, we shall find in each that a few or a many of these letters drop out. They do not, however, drop out, and this is one of the points I would emphasise—they do not drop out casually after a scattered, haphazard fashion, they stop out in little united or confederate gangs. Thus d to h may fail, and perhaps l and m likewise with them. For instance, cough and expectoration may fail—as in old persons or in the insane; and with their evasion the febrile group also may be absent, or, at any rate, insignificant. There seems, then, to be some method in these evasions; what is it? If by comparing a sufficient number of cases we are fortified in our notion that from the ideal type certain little parcels of symptoms often and indeed generally fail to appear, and this by some links, in some methodical way, why then by noting these innings and blanks we might put together some subordinate types, or hypotypes, and thereupon try to detect a corresponding parcelling of the causes. And having done this we might, on betaking ourselves to the bed-side, find ourselves enabled not only to refer the piecemeal cases to the respective hypotypes, but also to analyse the completer cases into certain associated or interpenetrating parcels of symptoms. For example, we might perceive in one case that cardio-arterial, vaso-motor,

and gastric symptoms were due in great measure to irritative processes in the bulb, while in another they were due severally to direct impairment in heart, lung, or stomach itself. In full complex cases no such discriminations could become possible unless the analysis had already been made by particular studies of the sundry piecemeal cases. When we have learned to pull a case in pieces and to discern the subordinate gangs of symptoms severally, we shall know how to interpret their respective sources and stresses, and thus to prevent or to alleviate them when mingled, or piled one upon another.

When, however, does a case of pneumonia—and I have taken pneumonia as a class for application to all classeswhen does a case of pneumonia, by such fragmentation as we have been supposing, cease to be pneumonia? When by such eccentricities would it forfeit its name? Well, frequently; as, on the margins of the class, cases fade or melt into cases of other classes, or into zones of anomaly. We began by declaring that classifications are all and each of them arbitrary concepts, and types but abstract ideas. But, even if we keep strictly within the four corners of familiar cases, there are many variations of the pneumococcic pulmonary diseases ordinary acute pneumonia, the pneumonia of children, that of the drunkard, that of acute mania, that of sepsis, and so on, to name but a few. We know besides that the pneumococcus is prone to attack other parts, such as the joints, the meninges of the brain, and other tissues, which events are effects of this particular specific link in the chain of causation. But beside this specific agent there are evidently large groups of other determining antecedents by which the issue is compelled in this direction or in that; broad variations which we may attribute to various antecedents, on the one side of the equation or on the other; on the part of the external causes or on the part of the individual. Or there may be rare or irregular determinants on both sides, when the analysis becomes more and more difficult. Yet these and such questions are of urgent practical importance. The pneumococcus, let us say, may vary much in virulence; but generally this kind of variation would affect rather the degree than the form of the attack. know, however, that microbes differ waywardly within their kinds, as is shown to us, for instance, in the group of which the B. coli is a familiar example. Again, such is the specificity of vital molecules that minute variations may so divert affinity that a toxic molecule may hook itself on to one organ rather than another, to an eccentric rather than to what we should call its normal attachment, and thus, perhaps, to an organ, geographically speaking, as far from its usual haunt as the knee is from the lung. Notwithstanding this, I think that partialities in the determination of a particular microbe to this organ or tissue or to that usually depend more on differences in each or either between one individual and another. When pneumonia, for instance, attacks several persons in the same household, the pervading microbe is presumably the same in quality in all the cases, yet in each of them the clinical series, the line of attack, may be very different.

Permit me now to illustrate these arguments by a few particular cases. Of ordinary acute pneumonia I need not describe an example. It would be after the accepted type, with the accelerated pulse and respiration, the pain, the characteristic cough, the rusty expectoration, &c., and would present the signs of consolidation of the lung.

With this "typical case" I will now compare the following. A young lady, in excellent health to all appearance, started with her sisters in a motor-car for a ball at a considerable distance from her home. On the journey she felt sick, then vomited. The vomiting continued, becoming, indeed, more severe, until she saw it was impossible to accompany her sisters to the house of her friends, and consequently was taken home. On her way back the vomiting became so bad that she had to lie with her head hanging out of the car. She had a restless night, but feeling better in the morning got up. At the lunch hour, however, she fell off again and returned to bed. The family were friends of mine, and being near them I saw her twice a day till the crisis was over; about the sixth day it set in favourably and she made a good recovery. But during the illness we were continually anxious about her. As regards the chest indeed it was not easy to discover the lesion. For three days at least I sought for a patch of the disease in vain. On the fourth day, if I remember right, I ascertained the presence of a small patch of pneumonia in the right axilla;

it was to be heard in the armpit only and over a small area. The expectoration was scanty, but the one or two sputa obtained were rusty and glutinous. The anxiety lay elsewhere—namely, in the behaviour of the pulse and respiration, for the pulse ran continually at 128-130 and the respirations at 55-60, and this although the patient was calm and amenable. She indeed did not make much complaint and had no apprehensions. And I desire to emphasise this—that from first to last she never had even a passing delirium. One almost doubted the reports of the nurses, but we were assured on repeated questioning that not even for one moment did she wander. The temperature was disposed to run very high, but was remarkably controlled by moderate doses of phenacetin, as if it was an incidental phenomenon. And as events fell out, the case proved to be a benignant one; we were unnecessarily apprehensive. With the crisis these alarming rates of pulse and respiration fell to the normal, and of the local trouble we heard no more. Here, then, we had a parcel of the disease, in most prominence a gang of symptoms referable to the medulla—namely extraordinary and persistent vomiting, rapid pulse, and rapid respiration—and these not due to pulmonary embarrassment, for the pulmonary condition, save as a criterion of diagnosis, was negligible, and cyanosis, often looked for, if present at all, appeared only in a fuller cherry colour of the lips. From such an example as this we learn, I think, that even in a typical case dyspnœa and quickened pulse may not always be due entirely—possibly sometimes not at all—to the lung lesion, but only in parallel with it, although, of course, the two parcels of symptoms may reinforce each other or be blended inextricably.

The second case I would quote is one I saw with Dr. H. B. Roderick of Cambridge; it occurred also in a young lady. In this case the pulse and respirations were not greatly disturbed; there was nothing in them to disquiet us. likewise, the pulmonary signs were difficult to verify. Dr. Roderick, who kept a vigilant ear to the chest, could not detect any physical signs of pneumonia till the third or fourth day, and then over a narrow and indefinite area at the back of one lung. A few days later, for the case did not clear up decisively about the sixth day but after a partial crisis relapsed, another patch, but also very moderate in extent and degree, appeared in the other lung, accounting for the relapse. But even then the total pulmonary symptoms were slight, and might, indeed, have escaped observation. Nevertheless, the case was a most alarming one. On both my visits, which were paid during the two acuter phases, the patient was in a hemicomatose state, with contracted pupils, some muttering delirium, and occasional muscular twitching. The nights were spent in violent delirium. The negative signs of the urine hardly allayed the apprehensions of uræmia, but as the second phase of the pneumonia subsided these cerebral symptoms also diminished. Cases of severe cerebral symptoms, especially of prominent delirium, are fairly well known in cases of pneumonia in which the pulmonary symptoms are inconsiderable; and in these the pneumonic patch is often at the apical portion of one lung. In this case, then, out of the typical series of pneumonia we had segments; the poison attached itself to the cerebral area, as in the former case it adhered to the medulla. But this is not all; on my return from the Long Vacation Dr. Roderick and Dr. Latham told me that after another abbreviated crisis the cerebral symptoms returned in all their severity with a small patch of pneumonia at one apex, and again the same cerebral series was repeated with a small patch somewhere else ("pneumonia migrans"). The bulbar symptoms were ("pneumonia migrans"). inconsiderable. It is probable, then, that in some of the completer cases the cerebral symptoms are not due merely to imperfect aeration of the blood; though of course they may be thus aggravated. But out of the complete series we may have the cerebral parcel, or the medullary parcel, and so on; and in each case it is important for the practical man, so far as may be, to analyse particular cases that he may discriminate the places of the component parts in the series. Or, on the other hand, whatever be the significance of the name, we may be dealing with pneumonias unawares; that is, cerebral parcels of it, or medullary parcels, with

¹ In my article on Paroxysmal Tachycardia in the new edition of our "System of Medicine" I have referred to two cases of pneumonia in which the pulse suddenly rose to 100 and more and subsided without much apparent significance. One of these cases held a moderate course throughout.

which the pulmonary, or cardiac, or febrile, &c., parcel may not coincide, or only in degrees so slight as to be latent. I recall a case I saw many years ago with Mr. T. Pridgin Teale in which some such illness was a riddle; cerebromedullary symptoms were almost desperately alarming, even to extreme and persistent Cheyne-Stokes respiration, and no sign of pneumonia whatever could be detected by three of us; yet convalescence was complete. I cannot now say the case was one of pneumonia, but its causes, initiation, and periods were not inconsistent with it.

I think I have said enough on this discrimination of short sections of the pneumonic series, as contrasted with the mere lapses of odd symptoms, to illustrate my point of view; but I would make a short digression to cases in which the pain is very severe and persistent. This I can scarcely describe as fractional pneumonia, for I am now contemplating cases in which the type as a whole is fairly represented. In my experience persistency and grievous severity of the pain forbode evil; indeed, I am disposed to go farther and to say that this sign is almost of fatal significance. I wonder if this is a general experience? I am disposed to think they are cases of a mixed (streptococcie?) infection, for reasons which I cannot now enter upon.

In conclusion, as I am writing on pneumonia I would venture to refer, somewhat irrelevantly, to a recent case of great practical importance, though its features lie outside my segmentary categories. It showed that thrombosis of the pulmonary artery—for such, no doubt, was the nature of the case—may establish itself without notable direct effect on the cardio-respiratory mechanism. A middle-aged man, a patient of Mr. C. G. Cory of Soham, was attacked with pneumonia, severely, but not to an extreme degree. The crisis set in duly, and at this turn of the case I remarked to Mr. Cory that the patient would now do well if no clot formed about the heart. I cannot say what made me make this proviso; I scarcely think there was then any sign of such a misfortune. In a few days, when, indeed, the case had passed out of my mind, I received a telephonic message from Mr. Cory saying that the patient was not doing at all well, and that so urgent was his discomfort that almost imperceptibly doses of brandy had increased to the amount of 12 ounces a day. He reported further that the pulse was 84 and regular, the heart's action undisturbed, the respirations moderate, and the temperatures normal. Thus reassured I suggested that the patient might be oppressed by the large quantities of brandy. Mr. Cory's reply was that they feared he could not do without it, as "he felt so bad." heard no more for two or three days, when I was informed that the symptoms in detail were as before, but the discomfort no less, and I was asked to see him again. On entering the room one saw directly that the report had not been overcharged; he had a distressed aspect, he was restless, and the face was too cool and moist, and was rather, but decidedly, livid. Yet even then no abnormal signs were to be made out. The pulse was 84, and irreproachable; the respirations within moderate limits, and the sounds of heart and lungs-except, of course, trifling remnants of the pneumonia-were without any defect of quality, or any addition. I listened to the heart twice or thrice and for long periods, probably for five minutes at a time, but even then was unable to detect the slightest murmur or irregularity. Mr. Cory, whose examinations were frequent, had never heard any fault. Notwithstanding, thrombosis was an unavoidable diagnosis. A day or two later when the nurse was making her records, and had just counted the pulse-still ranging about 80-84, and regular-she turned aside to enter the number on the chart; as she was making the entry at the bedside, scarcely more than a second or two had elapsed, she heard a sound, the pulse had stopped, and the patient was passing away. We are but too familiar with these cases of thrombosis, but in my experience a per-sistently steady cardiac and respiratory rate, rhythm, and quality up to the moment of death is unique. No necropsy was made.

Cambridge.

CENTRAL LONDON THROAT AND EAR HOSPITAL.— The winter session of this hospital was opened on Nov. 8th, when Mr. Charles Ballance, M.V.O., delivered an address entitled, "The Lesson to be Learnt in London from the History of the Mastoid Operation."

ON RADIUM IN THE TREATMENT OF CANCER AND SOME ASSOCIATED CONDITIONS.

BY HENRY T. BUTLIN, D.C.L., LL.D.,
PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND;
CONSULTING SURGEON TO ST. BARTEOLOMEW'S HOSPITAL.

MANY times during the last year I have been asked whether radium is of use in the treatment of cancer. I propose to give a short account of my experience on this very weighty question.

Up to 13 months ago I had only been in the habit of sending cases of rodent ulcer to be treated with radium by Dr. J. Mackenzie Davidson. The results of the treatment appeared to be excellent in most of the cases I had seen, but the disease was of small extent in all of them. The only instance in which radium had been used for epithelioma was that of a gentleman in whom a chronic ulcer of the inside of the cheek, in the midst of long-standing leucoplakia, had been cured by radium. The application had been followed by a good deal of superficial inflammation, but the ulcer had healed well, and the scar was good. The ulcer recurred, for the patient would smoke several cigars a day. It was again treated with radium, but did not improve, and Dr. Mackenzie Davidson advised him to ask me to remove it. But he persisted in desiring the application of radium, which was used under protest until the ulcer became an epithelioma and the glands of the neck became affected.

In September of last year (1908) I attended the meeting at Brussels of the International Society of Surgeons, of which Professor Czerny was President. There I saw Dr. Abbé's (New York) models of malignant disease before and after treatment with radium, and I came to the conclusion that if he could cure such cases as these appeared to me to be, he must be able to use radium with much greater success than any person in London. He also exhibited a model of the tongue of a patient with very severe leucoplakia and ichthyosis, and there was a label by it to say that it had been cured by the use of radium. I was very much struck with this, for I have never seen or heard of the cure of such a condition either in this country or in any other. It is regarded as an intractable condition, and that is the opinion I have myself formed of it after some 25 years' experience. I therefore asked Dr. Abbé to show me the model of the cured tongue, telling him that I had always thought the condition incurable, and adding that if he could convince me he had cured such a tongue as his model suggested I would send patients from London to New York to be under his care for leucoplakia. His reply was that this tongue had been incidentally cured during the treatment of a severe condition of the cheek, and that he had no model of it. I was not satisfied with his reply, and spoke to one or two of the American surgeons with whom I was acquainted in Brussels, begging them to tell me what they thought of this case particularly. One of them told me he had asked Dr. Abbé the same question as I had done and was no more satisfied with the reply than I had been. I was informed by another New York surgeon that Dr. Abbé was more enthusiastic over radium than his colleagues were.

In the beginning of February of this year (1909) Sir Frederick Treves delivered a lecture on Radium in Surgery at the London Hospital, as an introduction to the announcement of the foundation of a British Institute of Radium. In that lecture he said: "With regard to epithelioma of the tongue and epithelioma of the lip, they are cured by radium. You say, of what degrees? I acknowledge that the cases are in the early stages of epithelioma; but they are epitheliomata that are ulcerating, and that, so far as we know, can yield to no other treatment except that of operation." This yield to no other treatment except that of operation." statement was so contrary to my experience that I wrote to Sir Frederick Treves and questioned him on the certainty of the diagnosis in the cases of cure of reputed epithelioma, and wondered why it was that we had had no success in such cases in London. I also mentioned my interview with Dr. Abbé. Sir Frederick Treves replied that he had no doubt of the diagnosis of the cases in question and was sure that they were genuine cases of epithelioma. He also told me that the reason of the lack of success in London and the reason of success in Paris was that radium was applied

J 2

by means of the disc in Paris, by means of the glass tube in London, and that Dr. Abbé employed the method by the disc and was therefore able to obtain such results as he had exhibited. Now for the cases I have actually seen.

CASES OF EPITHELIOMA.

CASE 1 .- At the end of September, 1908, I was consulted by a gentleman, between 50 and 60 years of age, on account of what I diagnosed as a flat warty epithelioma of the inside of the cheek, about 14 inches across. There were two little patches of leucoplakia, and a history of long-standing "something wrong" with that cheek. I thought I could detect a deep-seated but small gland at the angle of the jaw. I advised him to have the ulcer of the cheek and the glands removed, and gave him the names of two surgeons, so that he might select one of them for the operation. afterwards that he went to see both of them, and they had agreed with me in the diagnosis of the disease. It was finally arranged that one of these gentlemen should perform the operation. Some two or three months later, however, I met the selected surgeon, who informed me that the patient had been advised to go to a well-known dermatologist for treatment by means of radium, so the operation had never taken place.

After the publication of the lecture of Sir Frederick Treves I thought I should like to know what had become of Case 1, particularly as the specialist under whom he had placed himself was known to have been to Paris and to have studied the Paris method of applying radium. I sent for Case 1, who came to see me on Feb 10th, and told me that he had first been treated by ten sittings of 10 minutes each with the X rays in order to "bring the ulcer within the compass of the radium treatment." He had then been treated at longer or shorter intervals by the application of radium nine times for half an hour each time. The last application had taken place at the end of January. pain had been caused by the applications, and no inflammation had followed them, although there was usually a little occasional pain in the cheek for the first few days after radium had been used. The condition of the cheek quite surprised me. The sore was decidedly less than an inch across, and appeared to be quite superficial. It was more a raw place than an ulcer, but it was still very warty. The surrounding area was beautifully sound and soft, quite different from the scar of an operation wound. I was very much impressed by the improvement which had taken place. The glands were not perceptible.

I determined to follow up the case. In September I again begged the patient to come to see me. He replied that he was under treatment with radium in Paris on account of a "large ulcer which has developed upon the site of the epithelioma and which Dr. D—— assures me will soon be surely cured" I have this morning (Oct. 26th) received a letter from his doctor saying: "He is really no better. The ulcer is quite characteristic of epithelioma, to my mind it is larger—it is coming more towards the mouth. You can see the cheek is swollen externally—I examined the glands, but could not be sure if they were enlarged. He was in great pain and that is why he went to Paris."

CASE 2.—A gentleman, 56 years old, was brought to me from Belgium on April 5th of this year by a medical man who had not only been treating him but who was a personal friend. He had suffered from leucoplakia for many years, and about January or February, 1909, an ulcer formed on the left border of the tongue. He had sufficient medical knowledge to appreciate the nature of the disease, but kept his trouble to himself as he had determined not to have any part of his tongue removed. But at the end of two months he showed it to his medical man, at the same time telling him that he would not have the disease removed. They went together to Paris, where he underwent treatment by radium and was subjected to the influence of the material for 25 hours in many sittings. After his return to Belgium he underwent further treatment with radium, until a gland became enlarged and the tongue became so painful that he could bear it no longer, and was therefore brought across the Channel to consult me. He was in a miserable condition, the fore-part of the left side of his tongue was esten away by cancer, and there were several easily perceptible enlarged glands. The skin over one of these was red from the recent application of radium. I sent him to a surgeon for operation, from which he died in the course of a few days. It

was very severe, for the glands were affected on both sides of the neck, and the tongue was very widely infiltrated.

This man's blood may be said, in a figurative sense, to have been upon his own head, for he concealed the existence of the disease for three months after he was aware of it, and absolutely declined an operation. I asked whether the Paris medical men had expressed either to him or to his Belgian friend and medical adviser an opinion that the case was not fitted for treatment by radium. I was assured they had not done so.

CASE 3.—On June 2nd of this year a gentleman, 70 years of age, was sent to me on account of a small ulcer in the floor of the mouth just to the left of the frænum. It was more a fissure than an ulcer, just under half an inch in length, and was surrounded by an area of induration which might be roughly estimated at one-eighth of an inch in width. It had all the characters of epithelioma, and there was very extensive and widespread affection of the glands, chiefly in the middle line and on the left side. They were hopelessly fixed. There was reason to believe that they had been palpable for nine months, but the ulcer in the floor of the mouth had only been observed for about a month. I cut off the posterior margin of the fissure for microscopical examination and sent it to Dr. G. L. Eastes for a report. The report was to the effect that the disease was malignant, and I agreed with the diagnosis on my own examination. Radium was applied in tube on three occasions. On June 5th Dr. Mackenzie Davidson applied four tubes for 20 minutes, and on June 7th the same four tubes for half an The tubes were of glass and contained in all 59 milligrammes of nearly pure radium bromide. They were covered with tin-foil 0.13 millimetre thick and thin rubber sheathing. The tongue was protected above by means of thick lead. On June 8th another similar application was made for half an hour. I examined the ulcer on June 25th, when it was smaller and less deep, and the edges were decidedly softer. There was no sign of inflammation in or about it. I examined him again on July 2nd, when the ulcer was quite healed and the surrounding swelling had disappeared. The scar was excellent, soft, and supple. As there was a little induration perceptible in the tissues a quarter of an inch below the surface I suggested that one more application of radium should be made. This was done and by July 29th the induration had completely disappeared. The condition of the floor of the mouth was so satisfactory that it was difficult to believe that an epitheliomatous ulcer had ever existed there.

The glands, however, remained enlarged and often gave him pain, so that he determined to go to Paris for radium treatment. On August 17th I received a letter from the operator to whom he was given in charge, telling me that the treatment had been commenced with two tubes each containing 0.05 centigramme of pure radium encased in 2½ millimetres of lead. It was intended to keep them applied for from 12 to 24 hours, probably on alternate days, for a fortnight, but the writer did not speak at all hopefully of the prognosis, at which I was not surprised. In fact, I received another letter on Sept. 30th to say that the patient had died on the previous day from rapid loss of strength and vomiting. The operator said the glands "had undoubtedly diminished in size. All the neuralgia disappeared some weeks ago." Gastric carcinoma was suggested as the cause of death. But as the patient had extensive affection of his glands and was suffering from albuminuria there seemed no reason to accept this explanation. Dr. Mackenzie Davidson told me he had published a case in which vomiting and high temperature had followed the application of radium to an extensive rodent ulcer, and he had attributed these symptoms to toxic absorption.

Case 4.—A gentleman, 70 years old, was sent to me on account of a small typical ulcerated carcinoma (epithelioma) of the left border of the tongue close to the foliate papilla. It was indurated, but only superficially, and would have been an excellent case for operation had it not been that there were glands enlarged and not very moveable from the angle of the jaw down to the bifurcation of the carotid artery. As the patient was very gouty and diabetic and had smoked a great deal and had been unsuccessfully operated on for cataract a severe operation appeared to be quite out of the question. But I thought radium might be applied to the primary disease and sent him to the dermatologist who had treated Case 1, asking him whether he thought the ulcer

might be cured by radium. His reply was: "There is every reasonable hope that radium will cure it and with very little pain." I have never seen the patient since. But his medical man wrote me on Oct. 8th to tell me that he had returned home and that the disease had made rapid progress both in the tongue and glands. "There is a large protruding ulcerated surface on the tongue." He further told me that Case 4 had had two applications of radium for one hour each time early in July on two following days, and then after a fortnight's interval he had had two more applications of an hour each on two following days.

There have been two or three other cases of epithelioma in which radium has been used with my knowledge or approval, but they were so advanced that success was not to be hoped for, and they ought not to be taken into the account. There is one case of esophageal stricture, almost certainly malignant, in which great improvement has followed the use of radium, but it is too early yet to speak of cure. Nevertheless, the patient seems to have received sufficient benefit from the application of radium to make it well worth while to have tried it.

The total result thus far is that, out of three cases of epithelioma of the mouth, which were all suitable for a local operation, only one was cured by radium, and that was of so small a size as to have merited the name trivial, if such a term can ever be applied to any malignant sore. In that case, however, the benefit to the patient was so great that it is difficult to exaggerate it. The removal of even so small an epithelioma of the floor of the mouth in a very unsound patient of three score years and ten must have been attended by considerable risk. The wound, if he recovered, might have taken weeks to heal, and he would have been subjected to serious discomfort and a good deal of pain for a long time. If the ulcer had been left, it was liable to enlarge and form a foul and exceedingly painful sore, which would have rendered the remainder of his life a burden to him. Four applications of radium sufficed to cure him without pain, and the cure remained permanent until his

On the other hand, two patients whose cases were deemed suitable for radium by the dermatologist who treated them were not cured. Case 4 does not seem to have been benefited. Case 1 appeared to be greatly the better for the treatment at the end of several months, but the improvement did not continue to a cure. The patient has been under treatment for a year; the sore seems to be larger than it was, and I cannot but question the action of those who took him out of the hands of the surgeon at a time when his disease was well within the reach of operation, and there was good reason to hope that the operation would have been successful. Radium, a year ago, was in quite an experimental stage in the treatment of epithelioma. It is so still, for I only know of one undoubted case of epithelioma which has been cured by it in this country. And the reported cures in Paris still lack detail and confirmation, particularly with regard to the extent and depth of the disease.

It is possible that larger quantities of pure radium and longer sittings may cure primary epithelioma in a much more advanced condition. If that be so, even if the glands must be removed by a surgical operation, the gain to the patient will be enormous, particularly in cases of cancer of the lip and mouth. The destruction will be reduced to a minimum, the scars will be better, and the after-results will be far superior to those which are left by operation, to say nothing of the advantage which the patient will gain in the absence of risk to life from the treatment and of pain during it. I hardly dare yet to believe that such results will be commonly achieved, but I earnestly hope so.

CASE OF DOUBTFUL NATURE (? EPITHELIOMA).

CASE 5.—A gentleman, aged 60 years, consulted me in July of this year on account of suspected epithelioma of the prepuce. He had been circumcised some 30 years ago but the prepuce had not been separated from the corona and behind it. The left side of the glans was the seat of thick patches of leucoplakia of many years' standing. On this side, also, the edge of the prepuce stuck prominently out at the lower part, and the front aspect of the projection was the seat of superficial ulceration, without inflammation, indolent, pale red, and dry. The whole projection was a little indurated and stiff. The glands were not perceptibly affected. I was not sure whether the condition was actually

epithelioma. If he had consulted a dozen surgeons in London it is probable six of them would have diagnosed epithelioma; the other six would have considered the condition not yet epitheliomatous, but almost certain to become so. I am quite willing to believe that it was a young, thin, and dry epithelioma. As excision of the affected portion of the prepuce would not, in my opinion, have sufficed, and it would have been necessary to recommend amputation of the anterior half of the penis, I sent him to the dermatologist who had treated Cases 1 and 4. On Oct. 6th he came to show me what had happened. The suspected epithelioma had completely disappeared, and there was no longer induration or stiffness of the prepuce in the place where it had been. The surface of the glans, which had been the seat of leucoplakia, was covered for the most part with yellowish thick crust, which had peeled off in one or two places, leaving slightly depressed and thin but sound scar-tissue.

Although, in the absence of actual microscopic examination, this case cannot be reported as a case of epithelioma, particularly as it had been, according to the statement of the patient, slowly forming for between two and three years, no one could have undertaken to declare that it was not epithelioma. And I am strongly in hope that it was a case of epithelioma cured by radium.

CASES OF LEUCOPLAKIA.

Case 6.—A lady, about 35 years old, consulted me in the spring of 1896. She had some elongated areas of thin leucoplakia some distance back on the under surface of each border of the tongue, larger on the left side. I attributed them to her gouty disposition and to the rubbing of her gold-crowned teeth against the borders of the tongue. By my advice her medical attendant snipped them away with a pair of scissors. In October, 1908, the right border remained sound, but an area of leucoplakia had recently formed on the left border. I sent her to Dr. Mackenzie Davidson for radium treatment. A single application of radium was followed, in the course of a week, by pain which endured about ten days. And the surface of the tongue was very sore. I saw the tongue on Dec. 3rd, when the plaque had disappeared, and all signs of inflammation had passed away.

On July 22nd of this year she came to tell me that, the same place having become "sore" once more, Dr. Mackenzie Davidson had again made a single application of radium about July 7th. No pain or inflammation had attended the application on this occasion. There was no sore place or plaque at the time I saw her, but the mucous membrane of that part of the tongue was a little thinner and paler than elsewhere.

CASE 7.—In October, 1903, I removed a large part of the right half of the lower lip for a warty epithelioma on the inner aspect, and a second commencing growth just below the angle of the mouth. A flap was turned up from lower down upon and beneath the chin to fill the defect. The glands in the floor of the mouth were widely removed at the same time. They had not been distinctly felt before the operation, but were found to be enlarged when they were removed. Microscopic examination proved epithelioma of the lip (I think in both places), but not of the glands. In spite of all I could do to dissuade him the patient continued to smoke heavily.

In August, 1906, he showed me a considerable area of thick and densely white leucoplakia on the inside of the newly formed lip, extending on to the toothless gum below and behind it. In November, 1908, the area had spread on to the gum, so as to cover a large part of it; the lip was thick and very tender, so that he had been obliged to give up smoking almost entirely. The surface of the new lip inside was very sore (excoriated). In February, 1909, he was much in the same condition, and complained that the lip was always very sore and tender, and that he had been obliged quite to give up smoking. I sent him to the gentleman who had treated Case 1. The patient was very much better in May of this year. The soreness and thickened condition of the lip were almost gone, and the fear of the occurrence of epithelioma in it seemed to have been averted. But the areas of leucoplakia remained precisely as when I had seen them last. I have not seen him since Sept. 22nd, two months after the last application of radium, when his lip was again beginning to be raw and tender here and there, although not nearly so bad as it had been in February. The leucoplakia was not altered.

CASE 8.—About three years ago I "trimmed" the borders of the tongue of a gentleman for chronic superficial glossitis, fissures, little ulcers, and areas of leucoplakia, with a suspicion of malignant disease at one spot. The parts removed were examined by the Imperial Cancer Research, but Dr. E. F. Bashford did not find cancer in them. On several occasions since then I have seen the patient because the mucous membrane below the scar to the left of the middle line has been irritated by the teeth and by the upper margin of a gold plate. Thin leucoplakia formed at this spot, and in the course of this summer there was a superficial chronic ulcer. He was advised to have it treated in Paris, and I thought that radium would cure it nicely. He went to Paris on Sept. 10th, where Dr. D- took charge of him. Radium was applied for an hour each day for ten days in succession, but I do not know in what strength (Sept. 14th to Sept. 23rd). He told me that the ulcer was quite healed by Sept. 28th. But two days later a similar ulcer formed just in front of where the former ulcer had been. He came to show me this ulcer on Oct. 21st, when I observed that the leucoplakia was just as when I had last seen it. I believe he is once more under radium treatment in Paris, and I hope the ulcer will be soundly healed. It seemed to me that he had been subjected to rather severe radium treatment for the cure of what appeared to be only a superficial indolent ulcer without any sign of malignancy.

(Note.—It may be interesting to medical men who are disposed to think that the fees for radium treatment in London are rather large to know that this gentleman told me he had to pay 2000 francs (£80) for his ten days treatment in Paris.)

to pay 2000 francs (£80) for his ten days treatment in Paris.) I do not yet know whether to advise patients suffering from leucoplakia to submit to treatment with radium. The thin area of leucoplakia in Case 6 was certainly removed, but it formed again about the same place within a few months. Of course, the cause had not been taken away, so that the recurrence was due to the continuance of the same conditions which I believe to have been responsible for the first occurrence of the disease.

The thick plaques of leuoplakia in Case 7 appeared to have been quite unaffected by the application of radium, but the plaques on the glans of Case 5 seemed to be in a fair way of being cured with the production of thin and depressed scars. The cure, therefore, if it takes place will resemble that due to superficial excision of the areas of leucoplakia, and I doubt whether the scars will remain sound in the interior of the mouth, where they are subjected to repeated irritation, and perhaps injury.

To sum up. So far, then, as treatment by means of radium in London is concerned, it appears to be admirably adapted to rodent ulcers of small or moderate extent. The application is painless or almost painless. There seems to be very little danger to life or health. The disease seems to be quite cured so far as we can at present judge, and the result is far superior to that which can be achieved by surgery. In cases in which the disease has attacked the bone or has made its way into the tear-duct or one of the accessory cavities of the nose I do not know what radium will do, for I have not seen such a case treated by it.

It is possible, by means of radium, to procure the healing of epitheliomatous ulcers of very small extent and to remove the induration around the ulcers. The cure of such conditions appears to be as satisfactory as the cure of rodent ulcers. In cases of epithelioma of any but the smallest extent, in my experience we are not yet justified in advising patients whose disease is amenable to operation to try the effect of radium unless there are circumstances in the individual case which render an operation inadvisable. far as associated affection of the lymphatic glands is concerned, I have not yet seen anything which would warrant me in believing that the application of radium to the primary disease, even if it were successful, would avert affection of the glands, nor have I seen any case in which undoubted secondary affection of the glands was cured or decidedly benefited by the use of radium. Whether the application of radium over the glandular area before it is obviously affected will be found by-and-by to exercise a protective effect upon the glands I do not know. At present the glands must be treated, as they have been hitherto, by operation.

The results which I have seen of the treatment of leucoplaka and allied conditions lead me to believe that radium only cures them by substituting thin scar-tissue for them,

but does not restore the mucous membrane to the condition it was in before the development of the disease. Treatment by means of radium in such cases has, however, the great advantage over surgical removal or the use of destructive agents that it is quite or almost painless, and that no actual inflammation and no open sore are produced by the applications when they are made by experienced operators.

To medical men who are disposed to send their patients to Paris, where there is a much larger quantity of radium than we have here, and where the operators have, in consequence, had a larger experience and are undoubtedly very skilful, I would venture to suggest that they should obtain a written statement from the operator that, in his belief, the case which they take or send to Paris is a suitable case for radium treatment, and is likely, in the opinion of the operator, to be cured by means of radium. Such a course will guard patients and their medical attendants from disappointment which might otherwise occur from an incomplete acquaintance with a foreign language on both sides and will give the operator to understand that the patient is not sent to Paris merely to be treated with radium in the hope that it may "do some good," but with the definite hope and expectation (on the part of the patient, at least) that it will cure the disease to which it is to be applied. The tuberculin boom is still fresh in my mind, when patients in even the last stages of consumption were sent or rushed off to Berlin to be inoculated. Berlin did a fine business while the craze lasted, but many of the patients spent more than they could afford to do on a treatment which was purely experimental, while others died miserably in hotels and lodging-houses.

Harley-street, W.

BRAIN AND MIND.

BY CHARLES MERCIER, M.D. LOND., F.R.C.P. LOND., PHYSICIAN FOR MENTAL DISEASES AT CHARING CROSS HOSPITAL.

In the crowded curriculum of the medical student, it is impossible to include everything that it is desirable for a practitioner of medicine to know; and it is perhaps not to be wondered at that in it psychology has no recognised place. Yet its problems are the most fundamental of all, and there is no subject that can occupy the human mind which does not rest ultimately upon some assumption in the domain of psychology. Does mind exist apart from matter? Is there any such thing as matter, or is it only a metaphysical assumption? What are the grounds of belief, of certainty, of likelihood? If brain and mind both exist, and are connected, what is the nature of the connexion between them? These are some of the fundamental problems which belong to psychology, and upon the solution that we formally, or, more often, implicitly adopt, depends the whole fabric of our Yet so little does a study of psychological conduct. problems enter into our schemes of education, that it is doubtful whether the majority of educated men and women do not believe that the colour of an object is in the object; though they would hesitate to assert that the sound of a gong is in the gong, and would probably deny that the prick of a pin is in the pin. That the three cases are on all fours, as the lawyers say, has probably not occurred to them.

Mind is often spoken of as a "function" of the brain. It may be, in a mathematical sense, a function of cerebral operations, though it would be an unwarrantable application of a term that has a precise meaning, to make an assertion of whose truth we are ignorant; but in a medical or physiological sense, mind is not a function of the brain. By the function of an organ we mean, or should mean, in medicine, the task that the organ performs in the economy of the body: we mean the physical effects of the activity of the organ. Thus, the function of bones is to give rigidity to the body, to give points of attachment to muscles, and protection to delicate structures; the function of muscles is, by contraction, to produce movements; the function of glands is to secrete and elaborate fluids; and the function of the brain is to receive, store, and liberate motion. The reception, storage, and liberation of motion is a physical, not a mental process. It is true that the function of the brain is not only to receive, store, and liberate motion, but to receive it discriminately; the motion of molar impact and pressure in one place, the motion impressed by sound waves

in another, the motion impressed by ethereal waves in another, and so on. And its function is not only to store, but to store discriminately; to separate and recombine streams of motion; to divert them here and there; to accumulate here and discriminate there. And its distributory function is not merely to pour out motion at large, as water is poured from a jug, but to distribute it to the various organs in definite quantities and proportions, so that each organ shall be governed to perform just so much function, for just so long, as is required,—the muscles to contract so as to move the limbs in certain directions and in a certain order; the glands to secrete at certain times and in certain quantities; and all the organs to take their proper share of the metabolism of the body. But for the regulating influence of the nervous system in the growing body, the legs would be of different lengths, and the arms of different sizes; and this we find happens when the nervous influence is interfered with by accident or disease. These then, are the functions of the brain; and, in enumerating them, no word has been said about any mental process. It is often supposed—at least people speak and write as if they supposed,—that there is one part of the brain for these purely physical and physiological functions, and another part in which mental operations go on. But a little consideration will show that this cannot be so. The constituted fundamentally alike. The whole of the brain is The neurons in one part have certain differences from the neurons in another, but throughout the brain we find neurons and nothing else, except their supporting framework and their nutrient vessels. If the neurons in one part store and carry motion, surely so do the neurons in another part.

The functions of the different parts of the brain differ, no doubt, in complexity, in elaborateness, in the part of the body that they regulate, and so forth; but, since the structure is fundamentally similar, the function also must be fundamentally similar. One part actuates the movements of the heart, another the movements of throwing a stone, another the movements of shoving through a crowd; but all parts have for their function the production of physical effects. Try to picture to yourself how the neurons of the brain —the branching fibres with their regulating cells and nuclei can produce or contain a sound of high C; the aspect of a cathedral; a smell of putridity; an emotion of anger, or a stomachache. It is impossible. You might as well try to tie these mental states up in a bundle with red tape and lock them up in a box. They are not in the brain; they are not in the neurons; they are not in the cells; they are not in the fibres. They are in the mind; and the mind is a universe by itself, distinct and disparate from all material things. There is no community of nature between the vibration of molecules in the neurons of the brain and the thoughts. passions and volitions that occupy the mind. There is an utter separation: between the mental and the material there

Yet the brain and the mind are, in our experience, inseparably bound up together. We know of no manifestation of mind except in animals with a nervous system; and, the more elaborate the nervous system, the higher, as a rule, the type of mind. Agents purely physical, applied to the train, produce startling effects on the mind, and even annihilate it altogether, temporarily or permanently; and no purposive action of the body is undertaken except after, and as a result of, that mental action that we call exerting the will. Notwithstanding, then, the gulf, impassable to human knowledge, that exists between the universe of matter and the universe of mind, the mind does appear to be conditioned by the action of the brain; the body does appear to be set in action by the operation of the mind. What, then, is the solution of the puzzle? What is the connexion between

The most truthful answer is that we do not know, and there is little likelihood that we ever shall know; but three hypotheses have been advanced to account for the connexion.

In the first place it is said that the processes in the brain produce the mental changes—that there are two sets of changes, mental and bodily, and that the latter are the cause of the former. In proof are adduced the many and incontestable instances of changes in the mind following immediately and directly on changes in the body. A pin is stuck into my leg; the nerve-currents started thereby pass up to the brain and there produce a feeling of pain. If

every mental change were preceded by a bodily change, this hypothesis would be plausible; but it fails altogether to account for the fact of volition, in which, as far as it is possible for us to judge, the bodily change does not precede, but follows the mental operation. This hypothesis is known as dualism.

The second hypothesis is that, when a brain process conditions a mental change, there are not really two changes, but only one. The brain-change and the mind-change are two aspects of one process, two sides of the same shield, separate to us because of the limitations of our mental capacity, but in reality but one. This is fascinating at first view, but when we look into it we find that it is a purely verbal proposition; that is to say, we are not capable, as indeed the hypothesis admits, of realising in thought the state of things which the words purport to express. It is a purely verbal explanation, and in reality is no explanation at all. This is what is commonly called monism.

Lastly, there is in the Leibnitzian hypothesis of parallelism, or pre-established harmony. By this hypothesis it is supposed that the two sets of changes go on together, always parallel to one another and simultaneous, but that there is no connexion whatever between them except that of simultaneity. The mental changes answer to the bodily changes somewhat as the movements of a man's shadow answer his movements, but without any relation of cause and effect between them. They happen together because the Almighty, when He attaches a mind to a body, ordains that they shall happen together, just as two clocks going at the same rate would move precisely together without being in any way connected. It is clear that this explanation explains nothing, and for none of the three can any reason be adduced why it should be adopted rather than the others.

But although we cannot explain the connexion between mind and brain, we can gain an inkling, or at least get the affair before our minds in a fairly intelligible form, if we look upon mental processes as an epiphenomenon imposed on the material processes of the brain. When an impression is made on the body from without, either by material contact, or by sound waves or light waves, or in any other way, a nerve current is set up which flows from the part impressed to the brain. Hence, after much wandering and many changes, it issues at length as an efferent current to the muscles, and produces a bodily movement. The circle of causation is closed. If our means of measurement were adequate we should find, on the principle of the conservation of energy, that every unit of motion was accounted for by material changes of position, and none was left for mental effects, supposing such effects possible. But at the turning point of the current occurs an epiphenomenon. Just as, in an electric circuit, the current flows completely round, but at the point of greatest resistance, where the flow is most impeded, a new phenomenon appears in the shape of a glow of light, so in the nerve circuit, the excess of resistance at one place is the condition of the appearance of an epiphenomenon, a mental change. The parallel is faulty, because in the electric circuit the epiphenomenon occurs at the expense of a portion of the energy, which disappears from the circuit; while in the case of the brain we do not know, nor can we conceive, that any portion of the energy is converted into mind; but the illustration is the nearest that the limitation of our faculties permits us to frame, and it is at any rate a real help in dispelling the notion that the production of mind is a function of brain, in any sense in which the term "function" is used in medicine.

Wimpole-street, W.

BRIGHTON AND ITS CENTENARIANS.—The town of Brighton is noted for its centenarians. For some time it has been producing them at the rate of about three in two years. The latest addition to the venerable roll is Mrs. Frances Norman, who on Nov. 5th attained the age of 100 years. She is the oldest inhabitant of the Brighton workhouse, and Mrs. Sinden, who occupies the bed next to Mrs. Norman, is only three and a half months her junior. Mrs. Norman is a native of Brighton and hardly ever has been out of the town. Although very deaf, she is in remarkably good health and has an excellent appetite. Brighton possesses three centenarians at the present time, including Mr. Jeremiah Simmons, the oldest gardener, who will be 102 in March.

CIVILISATION IN RELATION TO THE ABDOMINAL VISCERA, WITH REMARKS ON THE CORSET.

BY W. ARBUTHNOT LANE, M.S. LOND., F.R.C.S. Eng., SURGEON TO GUY'S HOSPITAL; SENIOR SURGEON TO THE HOSPITAL FOR CHILDREN, GREAT ORMOND-STREET.

WE hear a great deal of civilisation, as it is called, and the enormous advantages that accrue to humanity through its influence. Perhaps the most apparent advantage is the safeguarding the individual from the possibility of damage by his fellow creatures. While I would not wish to dispute the benefits which are derived from it, I would like to call your attention to the fact that there are many very serious disadvantages associated with it. These deal chiefly with the mechanical relationship of the individual to his surroundings. I do not propose to do more than call attention to the number of conditions which very materially shorten the life of the man who makes his living out of laborious pursuits, and limit in a corresponding manner his capacity for the enjoyment of life. These physical conditions represent the fixation and exaggeration of attitudes of activity, and are all progressively depreciatory, since they necessitate a shortened life, not only of the joints affected, but of the entire body. Again, the fixation of attitudes of rest, such as lateral curvature, flat-foot, knock-knee, &c., has a similar damaging effect, both on the altered joints and on the body generally, and materially affects the length of life and the capacity of enjoyment of the individual.

What I wish particularly to call attention to is the disadvantage that the individual experiences from the habit of keeping the trunk constantly erect. This habit of keeping the trunk erect from morning to night, whether the erect or sedentary attitude is assumed, is almost universal in the condition of civilisation which exists with us in the present day. It is necessitated by our habit of using chairs and by the fact that circumstances and surroundings do not lend themselves to our lying or squatting on the floor. The erect posture affects men and women differently, for the reason that the abdomen of the woman is relatively much longer than that of the man, while the female thorax and pelvis differ materially from the male. The abdominal wall of the woman is al o rendered less efficient by pregnancy and by the

support af or led by her dress.

To reiterate, I would formulate three general principles. When an attitude of activity is assumed on a single occasion certain tendencies to change exist. If this attitude is assumed habitually these tendencies to change become actualities, and the skeleton varies from the normal in proportion to the duration and severity of the attitude. The skeleton is first fixed in the attitude of activity, and later that attitude is progressively exaggerated. The same is true of an attitude of rest assumed on a single occasion and also when assumed habitually. The skeleton of the ordinary or normal individual rests upon a combination of the tendencies to change consequent on the assumption of complementary attitudes of activity and of rest. Now, when the trunk is erect, there exist tendencies to the downward displacement of the viscera contained in the abdominal cavity. several viscera are influenced by this tendency in a varying degree in proportion as they themselves vary in weight. For instance, the stomach and the large bowel are probably the most variable in weight, since a quantity of material collects in them and passes along at a comparatively slow rate. The more or less fluid nature of the contents of the large bowel assists in its accumulation at certain points, as, for example, in the cæcum and in the middle of the transverse colon, while in the stomach the pressure is exerted on its convexity.

The mechanics of the abdominal wall are such that the muscles exert a firm pressure on the viscera and tend to prevent their downward displacement. Still, in the abdomen, as well as in the body generally, the anatomy is so arranged that there must be a suitable relationship between the attitudes of activity and those of rest, or, in other words, that the erect posture, in which the viscera tend to drop, must be alternated sufficiently with a position in which all strain

assumption of the recumbent or of the squatting posture. In the former the viscera tend to displace upwards by their own weight, while in the latter they are forced upwards by the forcible apposition of the thighs. In our state of civilisation the recumbent posture is only assumed at night, and even then only partially, since the heavy buttocks and thighs sink deeply into the bed. The squatting posture, so common among savage races, is never employed. Therefore with us, from an early hour in the morning till a late hour in the evening, or for at least 16 out of the 24 hours, the tendency to drop of the viscera exists, while during the night this tendency is more or less in abeyance, but in a degree below the normal of the savage.

Nature deals with this modification of the normal mechanical relationship of the individual to its surroundings in precisely the same way as it deals with any specialised mechanical function, whether active or passive. First, as regards the large bowel or cesspool of the gastro-intestinal tract: it attempts to oppose the downward displacement of the cæcum into the pelvis by the formation of peritoneal bands, not inflammatory in origin, but functional, if I may so use the term, which pull upwards the hepatic flexure and secure it with as much firmness as possible in the upper and back corner of the right Acquired bands secure the outer surface of the loin. ascending colon and excum in a similar way to the peritoneal lining of the adjacent abdominal wall. They also grasp the appendix, commencing at its base and forming a new mesentery, which is more or less distinct from its normal mesentery. In this way a portion of the appendix takes on the function of a ligament of the cæcum, tending to oppose its downward displacement. Unfortunately for its new function, the appendix being a hollow tube whose mucous membrane secretes fairly abundantly, it is ill adapted for this purpose. The pull exerted by the heavy loaded cocum upon such of the proximal portion of the appendix as is fixed by acquired adhesions to the abdominal wall produces a kinking of the appendix at the junction of the fixed and mobile portions. In consequence of this secretion tends to accumulate in the distal portion of the appendix and concretions form in it, or it may become more or less acutely inflamed, producing varying conditions of what is called appendicitis. And unluckily for the right ovary, the appendix becomes a near neighbour, and the irritation and annoyance of the ovary may result in a cystic degeneration of that structure. Again, the recurring menstrual engorgements of the ovary serve also to encourage the appendix to manifest the effects of its mechanical disability at these periods.

The transverse colon, especially when loaded, tends also to fall into and occupy the pelvis. The abnormal acquired fixation of the hepatic flexure in the right loin and of the splenic flexure in the left loin help to oppose the downward displacement. Some of the load is transmitted to the ascending and descending colon by means of acquired adhesions, which connect the descending and ascending portions of the transverse colon respectively to the ascending and descending colon. Above the connexion of these tubes is direct, exaggerating very much the kink at the flexures. Lower down the strain is transmitted along an acquired mesentery which stretches from The greater portion of the load is one to another. transmitted along the great omentum to the convexity of the stomach, which may itself be loaded up at the same time. This abnormal drag on the convexity of the stomach is met by the formation of peritoneal adhesions or bands, which attach the upper and anterior aspect of the pylorus to the under surface of the liver. The upper attachment commences in the vicinity of the transverse fissure and extends forwards along the under surface of the liver, not infrequently attaching the gall-bladder or its duct. The effect of this upward drag upon the pylorus and of the pull on the convexity of the stomach is to interfere with its normal functioning and to result in its progressive dilatation. The strain on the stomach is experienced along its upper margin, and especially on either side of the pyloric attachment. It would appear that in the male subject the tearing strain is greater on the upper aspect of the first piece of the duodenum, while in the female it is greater on the proximal side. This varying distribution of strain would be readily accounted for is taken off the viscera and the tendency for them to drop by the different form of the abdomen in the two sexes. is in abeyance. This latter may be obtained by the Again, if the liver itself is mobile and displaced, and the

pylorus no longer depends for support on it, the point of strain in the concavity of the stomach approaches the cesophageal attachment in a degree proportionate to the downward displacement of the liver. The importance of these points of strain is that in the presence of autointoxication these two factors produce engorgement of the mucous membrane, its excoriation, ulceration, and later its infection by cancer.

The descending colon acquires a connexion to the peritoneum lining the abdominal wall external to it, partly to fix it, and partly to transmit the strain exerted by the transverse colon through it. The loop formed by the sigmoid section of the large bowel falls into the pelvis and struggles with the execum, the transverse colon, and pelvic organs for the mastery. As the contents of the sigmoid are fairly solid, this piece of gut is a very unpleasant and obnoxious companion. Therefore Nature endeavours to fix it in the iliac fossa as a straight immobile tube connecting the descending colon with the rectum. This is effected in the manner already described-namely, by the development of acquired bands of adhesions resembling peritoneum in appearance. These tags connect first the outer surface of the meso-sigmoid and later the outer wall of the sigmoid to the iliac fossa, till finally a straight fixed tube, whose muscular coat is comparatively thin, with a partial peritoneal covering, replaces the original mobile loop. The left ovary is in immediate relationship with the outer aspect of the meso-sigmoid, and very frequently becomes involved in the tentacle-like peritoneal processes fixing the meso-sigmoid and later the sigmoid. Later it becomes embedded in the adhesions and then completely surrounded by them. After a time the ovary becomes cystic and enlarged, when it forms around itself a serous covering so that it moves freely in a cavity. This covering gives way, and when the aperture is sufficiently large the cystic ovary escapes. It continues to enlarge and elevates the cæcum, transverse colon, and stomach, and to a great extent meets the disabilities consequent on intestinal stasis, of which it is itself in this instance both the effect and the Unfortunately, these cystic ovaries are more often malignant than was originally supposed. In a large number of cases in which I have removed large cystic ovaries I have been able to demonstrate, beyond a shadow of a doubt, the presence of the nest or cavity in which the cystic ovary

In a certain proportion of cases the acquired tags or bands of peritoneum do not grip the meso-sigmoid uniformly owing to the escape of the centre of the loop. In this case they attach only the extremities of the loop, approximating them to one another and kinking both. In consequence, an obstruction exists at the junction of the descending colon and sigmoid, and again in a more severe form at the end of the sigmoid. In consequence of the latter obstruction the loop becomes abnormally large and nature's efforts being only partially effective produce a condition which is infinitely worse than the normal loop, and a so-called volvulus results. The fixation of the sigmoid as a straight tube is unfortunately associated with a diminution in its calibre and in its muscularity, and irritation, abrasion, ulceration, and cancer of the mucous membrane result. In some instances abscesses form in or about the wall of the fixed sigmoid in consequence of the traumatism to which it is habitually exposed from the passage of its cutents being rendered difficult by its fixation and limited colibre and muscularity. Associated with the intestinal stasis are the very serious symptoms that ensue from the absorption of toxins into the symptom.

The earliest feature is the inhibition of the respiratory centre, and accompanying this, and apparently consequent on it, is the very definite enfeeblement of the circulation. These patients depend more or less completely on their diaphragm for obtaining enough oxygen to carry on their mechanical relationship to their surroundings which becomes more and more modified as the condition progresses. This brings about the several resting postures with which we are all so familiar and which we attempt to cure by exercises alone, regardless of the factor which produces them. Their resisting power to the entry of organisms is subnormal and the organism which most commonly effects a foothold is tubercle. The younger the subject the more readily does tubercle appear to be able to invade some tissue damaged by traumatism, The pulse is very feeb'e and soft. While the trunk is fairly warm, a hand passed over the shoulder of a toxic patient

comes very abruptly at the level of the insertion of the deltoid on a cold zone, and this coldness becomes more marked as the hand descends to the fingers. The skin covering the back of the upper arm is reddish-blue, very thick and gelatinous in appearance and consistence. It is not infrequently rough from the presence of large prominent papillæ. This condition causes much distress to the mothers of girls who wear short sleeves. The skin of the forearm is bluish and marked into islands by lines of a darker hue which correspond to the superficial veins. The hand is mottled partly by blue, partly by yellow patches. The sensation imparted to the hand of the observer by that of the toxic patient is un-mistakable. It is cold and clammy, and moist on its palmar The ears are also bluish and feel cold, as also does surface. the nose, but to a much less degree. These symptoms vary considerably with the surrounding temperature, but are readily recognised in the warmest weather.

The pigmentation of the skin in these toxic people is a very marked feature. Like many of the symptoms which result from intestinal stasis, but in a greater degree, it varies with the colour of the hair. While dark-haired people show pigmentation in a very marked manner, those with red hair show it slightly or not at all. In some peculiar manner redhaired people appear to possess a comparative immunity to the effects of intestinal stasis. Except for the face, the areas that show pigmentation most conspicuously are those exposed to friction, such as the inner aspects of the upper parts of the thighs, with the adjacent opposing surfaces of the buttock, the spines and abdomen where the corset or dress presses, the axillary folds, the bend of the elbow, and the neck. Pigmentation commences in the eyelids, spreads over the mouth, side of the nose, and later over the cheeks.

Loss of flesh is a very serious symptom and is productive of necessity of many secondary troubles. In the pelvis the loss of fat aids in producing the elongated contracted cervix uteri and the flexions of the uterus which are so commonly present in these cases. In the loin it removes that elastic support which keeps the range of movement of the kidney in what is regarded as normal. The loss of fat in the face and neck produces an appearance of age, distress, and disappointment which is most pathetic, particularly in the young subject. The loss of muscularity is shown in a complete want of tone, the muscles being flaccid and in-elastic. In the case of the abdominal muscles this is particularly serious, since one important factor in controlling the position of the viscera is lost more or less completely. The individual is also unable to lead an active physical life because of the poor muscular development. The muscles are not only small and feeble, but become very soft and friable, so that they tear readily, and when sutured yield and afford no security to the ligature. The condition of the breasts is also a very important one. First, the upper and outer zone of the left breast, and later the same portion of the right, show changes. In the young subject they become hard and nobbly, and may be sore and painful at the menstrual periods. Later in life they develop a cystic change, which may be painless or may be associated with attacks of pain owing to the distension of one or more cysts. Still later these degenerating breasts are very liable to develop cancer. Though the degenerative change commences in the upper and outer zones it may spread to the entire breast. It is very much more common in the virgin, and only arises in the married woman when intercourse is abstained from or is very irregular. These toxic people have very little or no sexual appetite, just as they lose their appetite for food and even hate the sight or smell of it. Perhaps the most interesting and accurate description of the influence of intestinal stasis on the sexual appetite has been written by Rudyard Kipling in "The Light that Failed." I do not think Kipling knew that his heroine was affected by intestinal stasis and probably constipated, but he describes an individual with that accuracy of observation and power of description in which I believe he has no equal. I need not recall the redhaired companion of the heroine, as I am sure all are perfectly familiar with the characters in the novel.

Perhaps one of the greatest of the many great men of whom America can boast was Brigham Young; he by irrigation converted a very poor district into one of the most fertile of the United States. He also attempted to popularise polygamy, and his efforts in this direction were met by a success almost equal to those in the direction of agriculture. I am unable to form any definite opinion as to how his action was

influenced by the knowledge of the influence of intestinal stasis on women, and the benefit which these people derive from matrimony. His views on this subject certainly did not meet with encouragement in the United States, partly, I suppose, because of religious or legal objections, and probably to a great extent from the ignorance of the public and even of our profession on the subject of intestinal stasis. I am inclined to think that when women know more about the physiology of life they may exert some influence on legisla-This is more likely to develop, in the first instance, in tion. the United States, where both men and women hold broader views and are less tied by creeds and tradition than they are in the old world.

The mental condition which is brought about by autointoxication is most distressing. While it renders the subjects miserable, and unable to concentrate their attention on work or pleasure or to control their tempers, it makes them most unpleasant companions. An alcoholic woman may be cheerful under the influence of her drug, but in no circumstance does the toxemia of intestinal stasis produce other than a depressing influence on the mind and on the body generally. Medical men are very fond of calling this condition neurasthenia. These patients readily become melancholic. They frequently suffer severely from headache, either continuously or at intervals, and they awake in the morning with a headache, feeling they have obtained no rest or advantage from their sleep, and that they are just as tired and exhausted as when they went to bed. The world seems always chill and gloomy to them, quite apart from the intestinal pain and discomfort which they so often experience. My friends have often said to me that they were sure patients would never submit to such a serious operation as removal of the large bowel. They forget that to these sufferers life has no attraction, and the risk of the operation at least affords them a chance of escaping from it. I do not think that any patient has expressed to me the slightest anxiety on this score, but has most willingly grasped the opportunity of parting with his other troubles at all costs and at the earliest opportunity.

The patients usually suffer from abdominal symptoms, varying from a colicky pain due to obstruction at a fiexure or at the sigmoid, or to a flatulent distension of the stomach or intestine due to decomposition produced by the delay in evacuation of the contents, or to the presence of a pancreatitis or of gall-stones. These conditions have resulted, partly from a direct infection of the pancreatic or biliary ducts by organisms from the small intestine whose level in the small intestine has been materially raised by stasis, and partly from a reduced resisting power to organisms consequent on the auto-intoxication. This infection of the pancreatic and biliary ducts does not appear to take place in such cases of intestinal stasis as arise early in life. I have never seen it in patients in whom loss of flesh has been a marked feature before 20 years of age. Infection of the gall-bladder and later of the pancreas arises in stout patients who develop intestinal stasis at or beyond middle life. It would seem that the loss of flesh and of vigour consequent on the toxemia of intestinal stasis so affects the mechanics of the gall-bladder as to produce an accumulation of bile in it and in association with the infection of the ducts to determine the formation of stones in it. Here again intestinal stasis is responsible for an inflamma-tion of these structures followed later by a cancerous infection.

I have endeavoured to indicate the importance of the fall of the viscera in the erect posture. Obviously the most effectual means of meeting this condition is by the exercise of a sufficient pressure exerted appropriately on the lower abdomen. For a long time women have been in the habit of wearing corsets for the purpose of supporting their dress and of affording attractive outlines to their bodies. The English corset is disastrous in that it exerts a constricting encircling pressure on the abdomen about the lower costal margin and exaggerates the tendency to downward displacement of the viscera. The straight-busked French corset is much less harmful, and if skilfully made and applied serves to exert a moderate pressure on the lower abdomen. The corset that is most efficient is one that, while exerting a firm and constant pressure in a backward and upward direction on the abdomen below the umbilicus, leaves the upper portion of the abdomen quite free.

Owing to a want of knowledge of the pathology of intestinal stasis the corset has not received the attention it deserves, so that by far the most important factor in the treatment of intestinal stasis and of its effects has been left in abeyance. I would strongly urge its therapeutic value on the medical profession as being the most effectual means I know by which the trouble to which I have called attention in these remarks may be avoided or mitigated.

Cavendish-square, W.

ON RHYTHMIC INTERRUPTERS FOR USE IN ELECTRO-THERAPEUTIC WORK.

BY H. LEWIS JONES, M.D. CANTAB., F.R.C.P. LOND., MEDICAL OFFICER IN CHARGE OF THE ELECTRICAL DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL; LATE PRESIDENT OF THE BRITISH ELECTRO-THERAPEUTICAL SOCIETY,

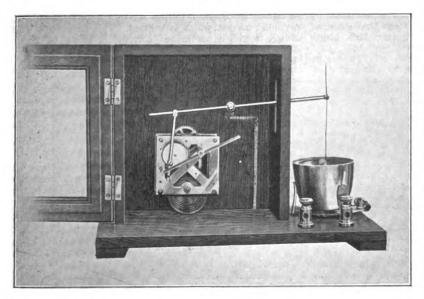

THE advantage of using regularly varying currents in many of the procedures of electrical treatment is gradually becoming more widely recognised, and although such currents have not yet come into general use, I consider that they are shortly destined to do so. One of the causes which have delayed their adoption has been the difficulty of obtaining apparatus for providing regularly varying currents,

but this has now been overcome.

During rhythmical electric stimulation the tissues stimulated are given recurrent intervals of repose in the course of the treatment, and time is thus given for renewal of blood-supply and fatigue is prevented. A sustained stimulation without any intervals tends to induce fatigue quickly, particularly in weak or paralysed muscles, and it is probable that harm may be done by electrical applications which set up a sustained tetanisation in such muscles. If experimental proof were needed of the value of rhythmic stimulation, it is to be found in the experiments of Débédat upon the muscles of young rabbits. He showed that rhythmic stimulation of the muscles of one hind limb for 10 minutes daily caused, after 20 days, an increase of 40 per cent. above the weight of the corresponding untreated limb. The current used was that of an induction coil. With continuous current also applied rhythmically the increase was only 18 per cent. When similar applications, but with no rhythmic intervals, were used the gain in weight was nil both for interrupted and continuous currents. Bordier, working with human subjects, has obtained similar proofs of the good effect of rhythmic currents, for he reports an increase in girth of half an inch in the arm after two months of rhythmic

By the term "rhythmic interrupter" is meant a mechanical device for turning currents on and off in a regular periodic manner, and there are two main varieties of rhythmic interrupter, giving different effects, and both are valuable in medical treatment. In the older type the current is simply switched on and off at a uniform rate, the change from "on" to "off" being abrupt; while in the newer type there is a gradual growth of current from zero to its maximum, followed by a similar gradual decrease to zero again. This is the most generally useful type of rhythmic interrupter, but the first type requires some brief notice, too. It will, perhaps, suffice to say that for sudden turning on and off of current a simple metronome with wires dipping into mercury cups and out of them fills the requirements completely. apparatus is well known in physiological work and is known as Kronecker's (more correctly Bowditch's) metronome. This type of rhythmic interrupter, in one form or another, has been in use since the very early days of electro-therapeutics. It is of very great utility in electrical diagnosis, and I have found it valuable in the treatment of wry-neck and of other spasmodic affections, and in functional aphonia. It appears that for these cases the steady rhythm of the make and break has a psychological effect of a useful kind, and when treating functional aphonia I insist on the patients counting in time with the beats of the instrument, with the same object. With this metronome the rate of the rhythm can be varied within sufficiently wide limits, and the duration of each period of flow of current can be regulated by adjustments of the mercury cups and the dipping wires to permit of the dipping wire to plunge either deeply or slightly, as

Fig. 1.

The second type of rhythmic interrupter—namely, that in which the current is made to rise slowly from zero to a maximum, and again to fall slowly back to zero—is the type which is more particularly valuable for many forms of electrical treatment. To effect this gradual change is a matter of difficulty, but this is overcome in the apparatus about to be described. (Fig. 1.) It consists of a train of clockwork which communicates an up-and-down movement to the end of a horizontal arm, and this arm carries at its end a vertical platinum wire which in its excursions dips down into a cup of water, penetrates nearly to the bottom of the cup, and then rises again until the extremity of

the wire almost emerges from the surface of the water. current passes from the wire to the cup through the water, and the resistance of this part of the circuit alters with the depth of immersion of the wire, and consequently the current passing through the circuit varies proportionately and continues to vary so long as the movement up and down of the platinum wire continues. greater the range of resistance in the cup the greater is the range of the current through the patient, who is connected up in the circuit in such a way that the current passes first through the interrupter and then onwards through the patient. To increase the range of resistance in the cup a small glass funnel is inverted in it, and the platinum wire moves up and down in this inverted funnel. When the point of the wire is at the top of its excursion upwards its point, though still immersed, is in the stem of the inverted funnel, and the resistance then is high and the current small. On the other hand, when the wire has descended to its lowest point it lies close to the metal of the cup, and is surrounded by a wider area of fluid, and the resistance is low, and the current, therefore, is large. It is easy, with this little contri-vance, to have a current varying rhythmically between 1 and 10 milliampères through a patient, and

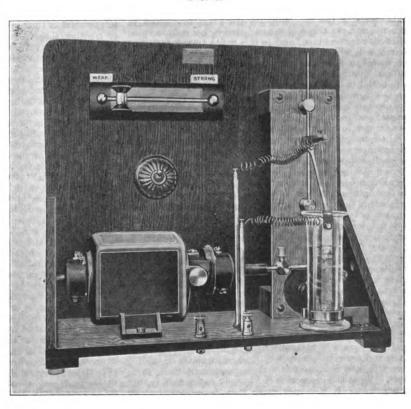

this gives as wide a range as is usually required. The rate or periodicity should be of about one complete cycle in four seconds or 15 per minute.

As the amplitude of the range of current through the patient de-pends upon the amount of the resistance which can be interpolated by the excursion of the moving wire, it follows that the liquid in the cup should have a high resistance and not a low one. To add salt to the water decreases the range of current very much. Tap water (or, better still, distilled water, by reason of its higher resistance) is the proper fluid to make use of in the cup. In order to adjust the platinum wire it is made to slide through a vertical hole at the end of the horizontal arm and can be clamped when in position, the best being when it can almost touch the bottom of the cup at the end of its downward range, and almost emerges from the surface of the water at its topmost position. This mode of fixing the platinum wire also permits of its easy

withdrawal for cleaning, and the metal cup is also free of all fixed connexions for the same reason. The current passes from the base of the cup to a metal saucer on which the cup stands, the cup and the saucer being made of a nickel crucible and its lid, which are inexpensive and eminently suitable. I have used a homemade apparatus of this kind for a number of years, the original instrument having been contrived out of a clock work photographic plate rocker. With this device either continuous or interrupted or alternating current may be regulated.

Fig. 2 shows a more massive apparatus of the same

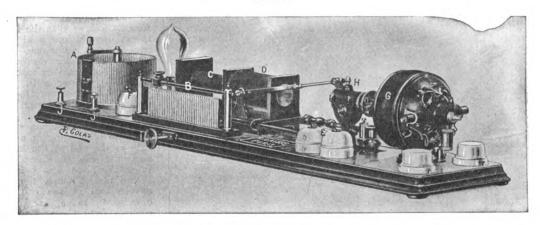

Fig. 2.

electric department at St. Bartholomew's Hospital for supplying rhythmic current to the electrical bath-room. It supplies five baths and works for several hours a day with great means of a worm wheel and gearing on the shaft of rhythmic current which is utilised. This apparatus, which the motor, as can be seen in the figure. This larger cannot regulate continuous current, is made by Messrs.

kind driven by an electric motor, which is in use in the slide to and fro upon guides over a primary coil in which an interrupted or alternating current is circulating. (Fig. 3.) The current in the moving secondary coil varies in strength as it approaches to, or recedes from, the fixed primary, and the smoothness. The requisite slow motion is obtained by variations in current in the secondary coil provide the

FIG. 3.

apparatus gives a sufficient range of variation without the Gaiffe of Paris (Medical Supply Association, 228, Gray's Innneed for the inverted funnel used with the smaller apparatus, road, London), while my own apparatus in both the small and a glass cylindrical container is used in place of the nickel cup.

Another very ingenious apparatus for the production of rhythmic currents is an instrument in which a small electric motor operates a crank which causes a secondary coil to road, London), while my own apparatus in both the small and large forms is made by Mr. Leslie Miller of 66, Hattongarden, London. The prices of the instruments shown in Figs. 1 and 2 are £2 15s and £7 10s. respectively, and the third instrument described costs £20.

harley-street, W.

THE TREATMENT OF CHRONIC ULCER OF THE LEG.

BY WILLMOTT EVANS, M.D., B.S. LOND., F.R.C.S. ENG., SURGEON TO THE ROYAL FREE HOSPITAL.

FEW will be found willing to dispute the statement that chronic ulcers of the leg often present great difficulties in treatment, and yet these ulcers can always be made to heal if sufficient care be taken, and in this paper I have described those methods which I have found of most value; they may prove useful to others who have to deal with this refractory condition. Before, however, I describe the methods I employ it is essential that I should point out the importance of an accurate diagnosis if success is to be attained. The etiology of the ulcerations met with on the leg is varied. Many are traumatic and in themselves need detain us little because a purely traumatic ulcer rarely becomes chronic, for it has a natural tendency to heal; in fact, if an ulcer which started from an injury is found to be still existing many months after its first appearance, it may be accepted as certain that some complicating factor is present which has interfered in

the healing process. I shall refer again to this point later.

In the opinion of most surgeons, so far at least as may be gathered from the text-books, the commonest cause of ulceration of the leg is the presence of varicose veins. would not for a moment be thought to under-rate the etiological importance of varicose veins in the production of chronic ulcer of the leg, for I recognise fully the great rôle they play in damaging the tissues of the leg and in preparing them for ulceration; but I wish to lay down as certain, at least to my own mind, that varicose veins are seldom the sole cause of ulceration of the leg. They cooperate, they aid, they form an important factor in the production of these chronic ulcers, but without other assistance they rarely suffice to produce definite ulceration.

What are these factors? Trauma I have already mentioned and sepsis is a potent adjunct in breaking down the tissues, and a certain proportion of chronic ulvers of the leg can certain'v be ascribed to the united action of these three factors. What the proportion is I cannot say definitely, but my impression is that not more than 5 per cent. of all

cases of chronic ulceration of the leg can be satisfactorily accounted for by these agents. The more I see of these chronic ulcers the more I become convinced that in a very large proportion they are syphilitic in origin—that is, they are due to the breaking down of gummata. In fact, I should feel inclined to say that more than 90 per cent. are syphilitic in origin. Such a belief must necessarily have a great effect on the method of treatment adopted, and my increasing confidence in the opinion I hold in this matter is due mainly to the effect of treating these ulcers by anti-syphilitic measures. not wish to deny that other etiological factors also have a share in the production of these ulcers; the presence of the syphilitic poison is not sufficient of itself to produce a chronic ulcer, otherwise there could be no reason why these ulcers should not occur on any other part of the body as frequently as on the leg. The poison needs, as it were, some excuse for appearing at one part of the body rather than another, and this localising factor may be trauma, sepsis, or varicose veins In fact, it is not rare for all these harmful influences to act together for the production of these ulcers. But the chief of them all, the most important, in fact the essential factor, is, in my opinion, the presence of the syphilitic poison. If that be so, the treatment to be effective must deal with this virus, though the other agents in the production of the ulcer must not be neglected. In addition to these ordinary forms of chronic ulcer met with on the leg there are other rarer varieties, such as that seen in Bazin's disease, which need not be described here.

If we search the text-books of surgery for a description of the characters which occur in gummatous ulcers of the leg we generally find it stated that the gummatous are more commonly met with above the middle of the leg-in fact, around the knee It is certainly true that ulcerations above the middle of the leg and in the neighbourhood of the knee are very frequently or almost always gummatous, but I hold that syphilitic ulcers are even more frequently seen in the lower half of the leg; so the mere fact that the ulcer is below the middle of the leg must not be allowed much value in the diagnosis of the cause The most important point in disgnosing chronic syphilitic ulcers of the leg is multip icity. (Fig 1.) If several ulcers are present the probability of the ulceration teing syphilitie in origin is, in my opinion, very great indeed, for it is intensely improbable, if varicosity of

the veins has led to so much interference with the circulation and nutrition of the part that ulceration has been produced in two adjacent fcci, that the intervening portion of the skin should have such good circulation as to enable it to retain vitality. (Fig. 1.)

Another character which is of great importance in diagnosing syphilitic ulcers is the appearance of the margin. It is often stated that gummatous ulcers are characterised by being "punched out" in appearance, with sharply cut This is certainly true of recent ulcers, but when the ulcerative process has proceeded for some months or years these well marked signs are no longer to be expected. in their place we have another character which is, in my opinion, not less trustworthy: this is the crenation of the margin. The edge is scalloped, the hollows being sometimes large, but in others very small, even needing a lens for their complete recognition. (Fig. 2.) I would not say that this crenation of the margin is absolutely diagnostic of a gummatous ulcer, but it shows at least that the ulceration is caused by the breaking down of a granuloma, and of all the granulomata the commonest in the leg is certainly the gumma. The presence of a "wash-leather slough," on which so much stress is often laid, is certainly very suggestive of a gummatous ulcer, but this sign also

The main object of this preliminary account of the etiology of these ulcers of the leg has been to draw attention to the very large proportion in which a syphilitic taint is present. Incidentally I may remark that no trust is to be put in the history of the case in the diagnosis of the gummatous nature of a chronic ulcer.

must not be looked for in chronic ulcers of the leg.

Is there any special reason for the slowness of healing in the more severe and long-lasting ulcerations of the leg? Fig. 3 is reproduced from a photograph of a specimen in the Museum of the Royal College of Surgeons of England. It shows the tibia and fibula of a leg; both bones are much thickened from chronic osteitis and periostitis, doubtlessly due to the persistent hyperæmia of the limb. But the most marked change is a broad long mass of new periosteal bone situated for the most part on the internal, subcutaneous surface of the tibia, a little above the middle, though the margins also stretch outwards on each side. This large mass of new bone has been produced by the proximity of a very chronic ulcer of the leg, and if we could dissect many of the older ulcers that we meet with in hospital practice we should find similar overgrowths and formations of new periosteal bone. During life the edge of the ulcer is adherent to the margin of the thickened mass of bone. Now, in the healing of any ulcer the drawing together of the opposite edges so as to diminish its size is a very important factor in its healing, so that the scar of an ulcer is never so large as the ulcer from which it was derived. When, however, the margin of an ulcer is fastened firmly down to a structure so unyielding as bone, not the least contraction can occur, and this in itself would go far to prevent or retard the healing of a chronic ulcer. Further, the firm fixation of the margin of the ulcer to the bone interferes greatly with a due supply of blood to the floor of the ulcer. and thus the formation of granulations is greatly impeded.

The main purpose of this paper is to deal with the treatment of these ulcers, and I may best commence by saying that everything which favours the general well-being of the patient will aid the healing of the ulcer. Therefore, the patient should obey the ordinary rules of hygiene in diet, and especially I would lay stress on the importance of total abstinence from alcoholic liquids for these cases: if this be not possible the amount of alcohol consumed should be reduced to the smallest limits. Excess of food is also harmful, but no very strict diet need be followed. There is no doubt that rest and elevation in bed are of noticeable value in expediting the healing of these ulcers; but rarely, indeed, can it be said that they are essential to a cure. Rest acts in several ways. When varicosity of the veins is an important etiological element in the production of an ulcer the beneficial effect of rest will be obvious, and it is well to bear in mind that even where no varicose veins are present rest in bed will greatly favour the return of blood from the part and the lymphatic circulation is also benefited by the recumbent posture, so that exuded materials are more rapidly and completely removed. The greater equability of the temperature in patients in bed also cannot be without a favourable influence on the regeneration of the tis-ues, so that we may have to fall back upon the employment of the

recumbent posture for those troublesome and otherwise intractable cases which fail to respond to the more simple methods of treatment.

The treatment naturally divides itself into two parts—the constitutional and the local measures. So far as the general health is concerned, I have already stated all that is necessary, and I have now to deal with the question of the medicinal treatment. Believing, as I do, in the gummatous origin of a vast majority of these chronic ulcers I look upon antisyphilitic treatment as of vital importance, and the only point to determine is whether that treatment should consist in the administration of mercury or of iodides My own impression is that, while the iodides far surpass mercurial preparations in bringing about the healing of gummatous ulcers, they have but little power in preventing the reappearance of ulceration a few weeks or months after the former ulcer has healed. This being so, the best treatment, in my opinion, is to give a course of iodides until the ulcer heals, and then to administer mercury so as to safeguard against the likelihood of a reappearance of the disease. The iodide salt to employ in the first instance matters, on the whole, but little; potassium iodide is most widely used, though in some cases the sodium salt is better borne. The dose required is often great, 20 grains three times a day being not rarely needed, but in many cases half this quantity will suffice. In those instances where the iodides are badly borne several expedients offer themselves; free dilution is the simplest and is generally very successful. Occasionally an increase of the dose is followed by a disappearance of the symptoms, but nowadays the most satisfactory method of dealing with such cases is the employment of organic compounds of iodine in the place of the metallic iodides. Recent chemical research has brought to light many synthetic remedies of this class, so that the surgeon has a wide choice. I have not tried them all, but of those I have employed I am inclined to think sajodin has been the most satisfactory. It must not be forgotten that it is the quantity of iodine which is absorbed into the blood that is of importance, and not merely the amount which has been taken into the alimentary canal. A very useful adjunct to the iodide treatment is to be found in the simultaneous administration of quinine. All iodides are depressing, and it may well be that in many very debilitated subjects the administration of large doses of such a depressant as potassium iodide may aggravate the locally depressing effects of the disease, and thus may lead to the extension rather than to a diminution of the ulcerative process. To its general tonic effects, as well as to its well-known antiseptic powers, I am inclined to ascribe the beneficent action of quinine in these most difficult cases.

Sometimes other tonics are also useful, and in suitable cases much benefit will be derived from the judicious administration of strychnine and of iron. Occasionally good may result from intermitting the administration of the iodides for a week or two. This is especially useful when an ulcer comes to a standstill after progressing favourably for some weeks. A short holiday, as it were, from the iodides will often be followed by an improvement in the condition of the ulcer which begins once more to heal with renewed energy. I consider it to be of great importance not to administer iodide and mercury at the same time, it is far better to administer them separately.

In all ulcerations associated with the breaking down of granulomata the presence of septic organisms is of the utmost importance, for they hasten the softening of the granuloma, they cause hyperæmia of the surrounding tissues, and thus favour the extension of the granuloma. By the absorption of septic products to which they give rise they impair the health of the patient and so favour the progress of the disease. It is not therefore unreasonable to expect that a successful attempt to diminish the number of septic micro-organisms of the part would be of great value in favouring the healing of the ulcer. Should the ulcer be very foul and foetid, dressing with frequent fomentations will favour the throwing off of sloughing tissues and will also, by promoting the formation of healthy granulation, lead to a less septic condition of the part tion used for the fomentation is of comparatively little importance; it should be antiseptic but there is no need in most cases to employ any powerful antiseptic, for the damage done to the tissues may surpass the benefit accruing from the fomentations. On the whole I am inclined to think that the most useful solution for this purpose is made

by dissolving a drachm of boro-glyceride in half a pint of hot water.

In most cases a lotion is advisable for the daily cleansing of the ulcer, and a great many which are suitable are avail-Those which I have found to be the most useful are lotio hydrargyri nigra, lotio hydrargyri flava, solutions of phenol and solutions of iodine. The local application of mercurials is not really inconsistent with the advice I have already given, that mercury and iodides should not be administered together. I am inclined to think that the yellow lotion of mercury is somewhat superior to the black lotion, but the difference is slight, and either will form a convenient lotion for chronic ulcer if diluted by the addition of three or four times the same quantity of water. Carbolic lotion must not be used strong; 1 in 80 or 1 in 100 will be quite sufficient, and the mild anæsthetic property of the phenol may prove useful in certain cases where the ulcer is specially sensitive. which ceases to discharge and heals under the crust so

use some ointment for dressing the wound. The use of an ointment prevents the dressing adhering to the surface of the ulcer, and if of suitable composition it will materially hasten the healing of the sore. Any of the ointments containing preparations of mercury may be used, though I think the ammoniated mercury and the yellow oxide are the most useful. It is well to bear in mind that if a mercurial ointment be used while the patient is taking iodides internally, but especially while a lotion containing iodine is used locally, there is no small risk of a chemical interaction taking place and of the red iodide of mercury being formed. This effect would be shown by the painful smarting resulting from the application of an ointment usually soothing and bland.

The dry treatment of these chronic ulcers is sometimes convenient and useful. Powders are applied to the ulcer in such quantity that all discharge is absorbed and within a few days the powder has formed a solid crust over the ulcer

Fig. 1.

Chronic gummatous ulceration showing crenation of margin.

Large periosteal outgrowth of bone. (From the Museum of the Royal College of Surgeons of England.)

But of all these lotions I prefer the preparation containing free iodine. It may be used in either of two ways. When used merely as a lotion for bathing the part night and morning, a lotion formed by the dilution of the tincture of iodine with four or five times its volume of water will do. It is no mean antiseptic, and it is able to exert its peculiar and special action on the gummatous deposit, and in this way the affected tissues get very much more iodine than when an ordinary dose of an iodide is given by the mouth. If, however, this latter effect is specially desired it is well to use a stronger solution, and a watery solution of iodine equivalent to the tincture may be employed with very good results. Occasionally I have thought it advisable to use even stronger solutions than this, but care and judgment are required in the selection of the cases on which a strong solution is to be employed. With the weaker solution no pain is caused, but the stronger solution may give rise to much discomfort and should only be employed when really necessary.

Between the applications of the lotion it is advisable to necessary, a window may be cut over the ulcer to give exit to

formed. This method of treatment requires much care in the dressing and is much more satisfactorily employed when patients have been admitted into a ward of the hospital or are kept under close observation at home. The essentials for success are that the powder should be perfectly dry and that it should be applied in such quantities as to absorb completely the discharge. There are many suitable combinations, but the following is perhaps the best of all: one ounce of the powder should contain three drachms of oxide of zinc and half a drachm of calomel, and the remainder should be formed of kieselguhr.

Unna's method of treating these chronic ulcers is especially convenient for those in which varicosity of the veins of the limb fills an important rôle. It consists in bandaging the limb from the toes to the knee with gauze, and while the gauze is being applied melted Unna's paste is painted over it. The paste solidifies as it cools and exerts a uniform and constant pressure on the limb both by night and day.

the discharge. Unna's paste consists of an admixture of gelatin and oxide of zinc. I recognise the value of Unna's dressing in certain cases, but I do not look upon it as a satisfactory routine method of treatment in chronic ulcer of the The elastic bandage introduced by Martin for the treatment of these ulcers associated with varicose veins is not without use, but the difficulty of keeping the bandage in good condition, especially when a copious discharge from the ulcer is present, and of applying it effectively day by day detracts greatly from its practical utility, especially in hospital out-patient practice; but in private work, where more care is likely to be taken both in bandaging the leg and in looking after the bandage, better results are attainable.

Gummata, like all other granulomata, are removeable by the application of X rays, and these may be employed usefully in some obstinate cases of ulceration of the leg which do not respond to the ordinary methods of treatment already detailed. The dose to be used should be what is often called a "half Sabouraud"—that is to say, an amount sufficient to cause one of Sabouraud's pastilles to undergo about half the change of tint which occurs when a full Sabouraud dose is given. The recognition of this quantity is naturally a little indefinite, for it depends so much on an estimate of tint, but a little more or less is of small importance. Indeed, a whole Sabouraud dose need not be too much. The other methods of treatment already described need not be interrupted except for the mere application of the X rays, being resumed immediately afterwards.

So far I have described the ambulatory treatment of these chronic cases. The task is rendered far less difficult if the patient is able and willing to rest—that is to say, to remain in bed for several weeks; but it is by no means easy to persuade these patients that confinement to bed is really desirable, and when they are willing to agree to this mode of treatment it is often not possible for them to avail themselves of it, because it interferes with their livelihood. Still, cases do occur from time to time; they are rare, it is true, but they do occur, where all the means at our disposal do not suffice to effect a healing of the ulcer while the patient is still walking about. In cases such as these rest in bed is essential. The ulcers of the leg which refuse to heal under the employment of ambulatory methods are chiefly those in which the varicosity of the vein is the most potent etiological element, especially when the limb is greatly swollen and the duration of the existence of the ulcer has extended over many years. The position in bed which is most conducive to recovery is one in which the leg is raised above the level of the rest of the body. This is best effected by placing a board under the lower part of the mattress with one end resting on the foot of the bed, so that while the upper half of the body lies flat the lower extremities are raised at an angle of about 30° with the horizontal. In this way the return of blood from the affected limb is greatly facilitated and the lymph also flows away freely with the result that the congestion rapidly diminishes, the size of the limb decreases, and the sore takes on a healthy healing action. Any of the topical applications which I have already mentioned in dealing with the ambulatory treatment can be now employed, but the best are the lotion of iodine and a weak mercurial ointment. The effect of the X rays may here also be taken advantage of, and in most of the cases a rapid healing of the ulcer will occur, but unless attention is paid to the antisyphilitic treat-ment there is great probability that as soon as the patient resumes his ordinary work the ulcer will reappear; therefore, even if the patient is treated by confinement to bed it is just as essential that the iodide and mercury in turn should be administered, as it is in the treatment of these ulcers by ambulatory methods. There are some ulcers that still prove resistant, even when given prolonged rest, and the delay in such cases will probably be due to the tethering of the edge of the ulcer to the underlying bone. It may, in these cases, be necessary to free this attached margin, and this is best done by first employing fomentations to reduce the septic complications of the ulcer, then scraping the whole of the ulcerated surface with Volkmann's sharp spoon, and with a scalpel undercutting the whole of the edge of the ulcer. It will often be found to be possible, when this has been done, to draw together the edges so that the size of the ulcer is materially reduced, and if at the same time the margin of the skin is freshened, a very thin border being cut off, the healing process will probably start afresh, and the granulation of the ulcer will be rapid and sure.

In speaking of a mode of causation of chronic ulcer of the leg I mentioned that trauma was often an important factor, and if this be true of the original ulcer it is also even more certain that the scar of a healed ulcer is peculiarly liable to be damaged by even slight injury, so that for long after an ulcer is healed care should be taken by a suitable dressing to protect the soft, tender, newlyformed skin from even those slight and numerous blows which to a healthy leg do no harm.

The difficulties of treating ulcers of the leg are certainly not small, but the satisfaction of causing to heal an ulcer which has lasted for 10 or even 20 years is very great, and the attainment of a consummation so devoutly to be wished may exercise all the care, attention, and ingenuity of the surgeon.

Upper Wimpole-street, W.

ATROPHIC PARALYSIS OF THE MUSCLES OF BOTH HANDS AND FOREARMS; RECOVERY.

(TOXIC DEGENERATION OF THE LOWER MOTOR NEURONS.)

BY R. T. WILLIAMSON, M.D. LOND., F.R.C.P. LOND., ASSISTANT PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY:

THE following are notes of a case of an affection which is of interest, since the diagnosis and prognosis of such cases

often cause much difficulty in medical practice.

A woman, aged 24 years, was admitted into the Manchester Royal Infirmary on April 20th, 1908, on account of atrophy and paralysis of the muscles of the hands and of certain muscles of the forearms. The patient had been in good health until the previous January, when she suffered from an acute illness in which there were nasal catarrh and pains in the limbs and muscles of the trunk. This illness was in the limbs and muscles of the trunk. thought to be influenza. The severe symptoms subsided in a few days, but she was unwell for three weeks. The pains soon disappeared in the legs and trunk, but continued in the arms and hands. These pains were of a dull aching character, and the arms were tender when touched. At These pains were of a dull aching first there was difficulty in moving the arms on account of the pains; but when the pains had subsided the patient noticed that there was distinct weakness in the movements, and the weakness increased until there was marked paralysis of the muscles of the hands and forearms. The arms had been paralysed for a month before admission to the hospital. There was no history of lead poisoning or of any of the symptoms caused thereby, and the patient had not used any substances containing lead in her work (in a cottonmill).

On admission to the hospital there was well-marked atrophy of the thenar, hypothenar, and interessei muscles of both hands, with inability to perform the movements normally produced by the action of these muscles. She was quite unable to oppose the tips of the thumbs to the tips of the fingers; she was unable to abduct or adduct the fingers, or to place them in the "interesseal position" (flexion at the metacarpo-phalangeal joints and extension at the phalangeal joints). There was also wasting of the muscles of the forearms, but this was less marked than in the muscles of the The wrists and fingers were "dropped." She was hands. unable to extend the wrists or to extend the fingers. The grasp and the flexion of the wrist were very feeble on the right side, but were only slightly impaired on the left. Flexion at the elbow was impaired on each side; extension at the elbow was performed quite well. The wrist-jerks and the triceps-jerks were lost. The muscles of the forearms were tender on pressure. The sensations for tactile impressions, pain, and temperature, and the vibrating sensation were felt on both hands and forearms. The legs were unaffected; the knee-jerks were present; there was no ankle clonus; the plantar reflex was normal (of the flexor type). There was no blue (lead) normal (of the flexor type). line on the gums. The heart, lungs, abdominal organs, and urine were normal. There were no other signs of disease.

The condition remained stationary for several weeks; then gradual improvement occurred, the muscles of the forearm recovering before the small muscles of the hands. Early in June, 1908, she was able to extend the wrists, but not the fingers, and the wasting of the muscles was not so marked. Two months later the muscles of the forearm had recovered completely and the fingers and wrists could be extended and flexed quite well; but the atrophy of the small muscles of the hands persisted and the movements performed by these muscles were much impaired. The hands presented a "claw-like" appearance (main en griffe). By the end of 1908 the wasting of the muscles of the hand had almost disappeared; she was able to perform the movements caused by the interessei, but she was still quite unable to oppose the tips of the thumbs to the tips of the fingers. During the first five months of 1909 steady improvement occurred; by the end of May the atrophy of the muscles of the hand had completely disappeared, and all the movements of the hands and forearms could be performed quite well except that in attempting to oppose the tips of the thumbs to the tips of the fingers she was not quite able to place them in contact. By the end of August these movements could be performed. The treatment had been massage, galvanism, and hypodermic injections of strychnine at different periods, and quinine pills during the last three months.

Briefly stated, the case was one of atrophic paralysis of the small muscles of the hands and of the extensors of the fingers and wrists, with paresis of the flexors of the wrists and fingers. The small muscles of the hands were next and fingers. The small muscles of the hands were most affected and were the last to recover. The onset was subacute. There were pain and tenderness in the arms at first The affection followed an acute illness supposed to be influenza. There was no evidence whatsoever of lead poisoning, and the symptoms differed from those of lead paralysis by the presence of pains and tenderness in the arms at the onset, by the paralysis and wasting being most marked and persisting longest in the small muscles of the hands, and by the affection directly following an acute illness (probably influenza). The quite symmetrical distribution of the paralysis, the complete recovery, and the pains and tenderness in the arms at the onset were against acute anterior poliomyelitis. Moreover, it is extremely rare for acute anterior poliomyelitis to affect both sides of the cord at the lowest cervical and first dorsal segments without affecting other regions of the cord. The case closely resembles those which were first described by Dr. A. Stanley Barnes 1 under the name of "toxic degeneration of the lower motor neurons." In his cases the muscles of the hands were chiefly affected. The pathological examination in one of his cases showed changes both in the nerve cells of the anterior horns of grey matter and in the peripheral motor nerves I have seen four cases of this affection and have recorded one case previously 2; in this case the patient has suffered from two attacks subsequently. Complete recovery has occurred after each attack.

Manchester.

THE

ENUMERATION OF BLOOD CORPUSCLES BY SIMPLIFIED METHODS.

BY ROBERT SAMUT, M.B., C.M. EDIN.,
LECTURER ON PHYSIOLOGY AND ASSISTANT TO THE PROFESSOR OF
PATHOLOGY, MALTA UNIVERSITY.

The enumeration of the formed elements of the blood, although admittedly of paramount importance in the diagnosis of disease, is not as frequently carried out as its value would call for. This is undoubtedly due to the fact that, in enumerating blood corpuscles by means of Gowers's or the Thoma-Zeiss hæmocytometer, the chief difficulty encountered is the necessity of counting the large number of corpuscles in each of the 16 small squares which make up one of the large squares, since at least eight sets of 16 small squares should be counted before a fairly accurate result can be expected. Moreover, corpuscles often overlap the lines which form the squares, and great care is required and time lost to avoid counting them twice over.

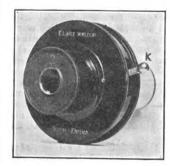

By means of the Blenden-Ocular "Ehrlich" these difficulties are avoided. The construction of the ocular is as follows. An ordinary No. 2 ocular is provided with a screen which cuts out a square from the field of vision of the ocular. By means of the little knob κ (Fig. 1) this square can be appeared out to be stated to be seen as the square of the little knob κ (Fig. 1) this square can be

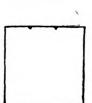

narrowed and reduced to 0, and by means of notches, which divide one side of the square into four equal parts, the reduction may be effected in exact proportion (Fig. 2).

Enumeration.—With this instrument enumeration of corpuscles is done as follows. The drop of blood

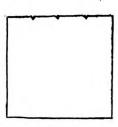

FIG. 1.

is obtained and diluted in the Thoma-Zeiss pipette and blown out on to the Thoma-Zeiss ruled slide in the usual way. When this has been placed on the microscope, allow five minutes to elapse. Use a No. 9 Leitz objective and a Blenden-Ocular, the slit being so adjusted by means of the little knob that four squares

of the central platform of the counting chamber just coincide with it. The number of red corpuscles are counted and the preparation may now be shifted as many times as desired, each count representing the number of corpuscles in four squares, since the slit corresponds exactly to four of the squares. The total fumber obtained after several such counts being divided by the number of counts gives the number of red corpuscles per field of four squares; hence division by four gives the number per square. This number multiplied by 4000 would represent the number of corpuscles per cubic millimetre were it not that the dilution has to be taken into account, and accordingly the result must be multiplied by 100 or 200.

Example: Average number of red corpuscles per square = 10. Then $10 \times 4000 \times 100 = 4,000,000$ per cubic millimetre.

The method is quicker and more accurate than that usually employed, since it enables a much larger number of squares to be counted irrespective of the lines of the counting chamber, which constitute an element of confusion in the process of counting.

Again, the Blenden-Ocular may be used for the purpose of counting the leucocytes in the following manner. A dry film preparation of the blood to be examined is fixed and stained by Leishmann's or Jenner's stain. Using a No. 9 Leitz objective and a Blenden-Ocular the number of red and white corpuscles are counted, the shutter of the ocular being at one-half or one-quarter of the total field of vision. The count is made several times through the same slit and an average of corpuscles per field is obtained.

Now
$$L: R:: l: r^*$$
 $\therefore L = \frac{Rl}{r}$

where L represents the unknown number of leucocytes, R the known number of red corpuscles per cubic millimetre, and 1 and r represent the average of leucocytes and red corpuscles respectively per field of vision.

¹ Brain, 1902, vol. xxv. ² Ibid., 1903.

A ship's steward, aged 30 years, was admitted to the made. The wounds were closed in layers. The adhesions Cardiff Infirmary under my care on Dec. 19th, 1908, with were broken down prior to wiring. Bending after wiring

On the following history. August 12th, while on board ship at sea, he was carrying dishes down the ladder from the bridge deck to the main deck. Tropical rain was falling and the steps and rails of the ladder were wet and slippery. His face was away from the ladder because of the dishes he was carrying. On one of the first three or four steps one foot slipped and he fell. He let go the dishes, threw his body backwards to save himself and the toes of his feet catching in the steps he came to the bottom of the ladder in the position shown in Fig. 1, both his knees striking the deck hard at the same moment. There was no medical man on board. The captain found both knee-caps broken, had him placed in his bunk, applied back-splints with footpieces and brought the broken fragments as near together as he could with plaster. The patient was kept thus until 19 days later, when the ship reached Durban, Natal. He went at once to hospital. Splints were continued for a week and then plaster-of-Paris was applied. He began to get about and on Oct. 29th left the hospital and

right. Pain in the knees was almost constant. Both patellæ were fractured transversely, the upper fragment in each case being the larger. The separation was 1 inch on the right side and $\frac{1}{2}$ inch on the left side. The knees were fixed by adhesions in almost extended positions. Operation was delayed in order to cure boils on the legs.

On Jan. 11th, 1909, operation was undertaken. Both fractures were freshened and wird, vertical skin incisions being made. The wounds were closed in layers. The adhesions were broken down prior to wiring. Bending after wiring

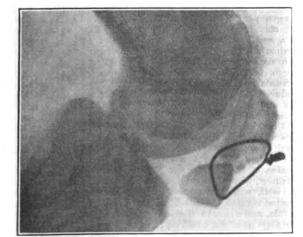

1G. 1.

Sketch showing dramatically the manner in which the knees struck the deck.

and before closing the wounds could not be done as the wires began to cut through. The wounds were healed in a week. The after-progress was slow in spite of massage and move-ments. The patient left the hospital on March 20th, using crutches. On June 9th he was still using crutches ("compensationitis") but could walk without them and bend either knee to nearly a right angle. M. Lucas-Championnière, who was in Cardiff, kindly examined him and pointed out that union was not firm in the right patella. On Sept. 6th he had discarded crutches and sticks. He walked well with a natural gait, his walk showing no evidence of his injuries. He had got fatter, was cheerful (in contrast with a former depressed condition), and was about to resume work. He still came downstairs clumsily, putting both feet on one step before proceeding to the next, but when encouraged and shown he managed to come down in the ordinary way. Both patellæ were firmly united and he could bend both knees to well beyond a right angle. The twisted ends of the wires could no longer be felt as

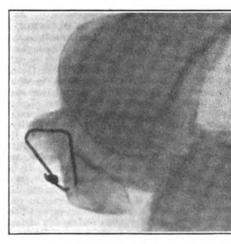

Fig. 3.

Radiogram of right knee.

came to England. On admission to the infirmary he could walk feebly with sticks. He had a great sense of insecurity, the slightest twist or slip caused him to stumble or fall; he held on to everything within reach. There was fluid in both knees and tenderness over both joint areas, particularly the

Radiogram of left knee.

came to England. On admission to the infirmary he could formerly. He had a pair of strong good legs and was quite walk feebly with sticks. He had a great sense of insecurity, satisfied with his condition.

A number of X ray photographs were taken by Dr. Owen Ll. Rhys in the electrical department of the infirmary. Those reproduced (Figs. 2 and 3) were taken on Sept. 14th and show the knees flexed but not quite to their fullest extent. In the left knee the wire, as frequently happens, having done its duty as a splint, is broken.

References.—1. M. Lucas-Championnière. This surgeon, whose experience of fractured patellæ is very large, on the occasion of his recent visit to Cardiff kindly told me that he had seen and treated three cases of simultaneous fracture. They occurred a good many years ago and he did not remember the mode of production in any. Two were in women and one in a man. All were old cases when operated on and in all one patella was sutured and not the other. As far as he knew all three patients had, eventually, useful legs.

2. Astley Cooper.² "A young woman was brought into my house in her father's arms and he said, 'I am obliged to carry her, for she has lost the use of her legs, having broken both her knee pans eight months ago.'" Recovery ensued gradually. 3. Hamilton: 3 "I have seen a double transverse fracture or a fracture of both patellæ in a man, set. 22, who fell from a third-storey window, striking, he says, upon his knees." 4. Mansell Moullin: 4 "The patient is conscious of something breaking before he falls and it sometimes happens that in the desperate effort to save himself the other patella snaps across as well. I have known this occur to a man in the first stride of a race." 5. Scudder: 5 an illustration is given of fracture of both patellæ, but there is no reference in the text.

Rarity of the injury.—There is little reference in surgical literature to simultaneous fracture of the patellæ, although fracture of the two bones at different periods and refracture of one bone are commonly mentioned. Simultaneous fracture appears to be a rare injury.

Mode of production.—I believe that in this case the fracture was due to direct violence. The very acute flexion of legs on thighs would bring the patellæ to the deck first and not the tibial spines. The patellæ would be held tight-braced against the femur ready to crack across directly they hit the deck. The patient's own statement is that he felt nothing snap before alighting and thinks that the blow on the deck caused the fractures. It is, of course, possible to take the view that in throwing his body backwards the man snapped both patellæ. The case must be regarded as a special one. As regards ordinary single transverse fractures, there seems in most cases to be no good reason for giving up the older view that each is due to the snapping of the bone across the condyles of the femur—i.e., to indirect violence. This is often clearly supported by the history of the case. Oardiff.

THE PARENTS' NATIONAL EDUCATIONAL UNION. The Thirteenth Annual Conference of this union will be held at the Friends' Meeting House, Bull-street, Birmingham, from Nov. 15th to 19th inclusive. On the opening day the members of the conference will be received by Mrs. George Cadbury, who will give an address of welcome, to which Earl Lytton will reply. In the evening of the same day an address will be given by Sir Oliver Lodge. Among the papers already announced for discussion are: "Environment in Relation to Nervous Stability," by Dr. Helen Webb; "Educational Ideals of the Renaissance and Ourselves," by Dr. Geraldine Hodgson, D. Litt.; "Direct and Indirect Moral Teaching," by Miss Bradley; and
"The Education of the Imagination," by Canon J. H. B. Masterman. Papers are also announced on the subject of university education by the Bishop of Birmingham and Mr. C. J. Fleet, the Governor of McGill University. In connexion with the conference and under the auspices of the Co-educational Public Schools Trust the co-education of boys and girls will be discussed under the presidency of Professor Hughes, Dean of the Faculty of Arts and Professor of Education in the University of Birmingham. During the course of the conference visits will be made to the village of Bourn-ville and to the new University buildings at Bournbrook. Among the principal objects of the union are the assistance of all classes to understand the best principles and methods of education, and the education of public opinion on the subject of the training of children. Further particulars of the conference and tickets (price 3s. 6d.) can be obtained from Miss Parish, 26, Victoria-street, London,

LARGE VESICAL CALCULUS, WEIGHING 261 OUNCES, REMOVED BY SUPRA-PUBIC LITHOTOMY; RECOVERY.

BY W. W. HEARNE, M.D., CH.B. MELB.

THE very large size of this calculus and the complete recovery of the patient will perhaps lend interest to the following notes.

A married woman, aged 39 years, consulted me in March of this year complaining of great pain in the pelvic region, foul-smelling urine containing much pus and frequently blood in considerable quantity, and frequent painful micturition necessitating her rising often as many as eight or nine times at night, with consequent loss of sleep and impairment of general health. She had been ill about 12 years, and had become rapidly worse during the last six months. Examination revealed a large calculus almost

entirely filling the bladder.

On April 15th Dr. J. H. Nattrass anæsthetised the patient, and the bladder having been washed out with boric lotion and its distension attempted with a few ounces of the same fluid, with Mr. A. Honman assisting, I opened the bladder in the suprapubic region with the object of removing the calculus by that route after having reduced its size by fragmentation. When exposed, however, all attempts at the latter procedure were rendered futile by the size and density of the stone, the largest lithotrite failing to grasp or even chip pieces off it; and as the use of the chisel and mallet appeared to offer too great risk of damage to adjacent viscera, it became necessary to remove the mass entire. It was obviously impossible to extract the stone through the limited space available below the reflection of the peritoneum, and the necessary room was obtained by carefully stripping that membrane upwards off the fundus of the bladder for about two inches. Even then it was necessary to incise the viscus from the extreme upper limit right down to the neck deeply behind the symphysis pubis. Venous hæmorrhage in the latter region was free but was readily controlled. After extraction of the stone the bladder was well washed out and the incision in it was closed above and below with catgut sutures, a rubber drainage-tube being inserted at about the middle; gauze drainage was provided in the prevesical region behind the symphysis, the ends of the gauze and the tube being brought out through the lower extremity of the abdominal wound, which was elsewhere closed. After four days the tube was removed from the bladder, which throughout the period of convalescence was irrigated twice daily with boric lotion and later with hydrogen peroxide solution (1 in 4), urotropin (10 grains) being also given by the mouth. On May 21st, as there was still a small urinary fistula, the walls of the latter were refreshed and brought together with a deep mattress suture, which six days later had to be removed as it was cutting through. After two days more the urine was coming through the fistula again. A self-retaining rubber catheter was then introduced per urethram and the bladder was washed out night and morning with boric lotion, followed by silver nitrate solution of strength increased from 1 grain to 5 grains in 4 ounces of water. At the end of eight days the fistula was permanently closed (nine weeks from the day of operation) and a week later the patient left the hospital. For another week the catheter was worn at night only and the irrigation of the bladder was continued night and morning. She is now, more than three and half months after operation, quite well, with her wound firmly healed and no cystitis. Her urine is retained perfectly and is passed easily at normal intervals, and she says that she was never better in her life, and "feels as if she could do the whole work of the house" her weight, which prior to the operation had fallen to 7 stones 12 pounds, is now 9 stones.

The calculus is nearly spherical, measuring 12½ inches in its longest, and 11½ inches in its shortest, circumference, and in the recent state weighed 26½ ounces.* A large area of its surface is thickly studded with sharp projecting spines, which, no doubt, were responsible for the hæmaturia from which the

^{*} Dr. Hearne sent us a photograph of the stone, but from the measurements given it will be seen that a reproduction of this at the actual size could not have been included in our column. The rester will easily imagine a spiculated blob about 25 per cent. larger than a cricket ball.

patient suffered. The stone has not so far been opened, so that no examination as to the composition of the interior has been made, but Mr. Masson of the University of Melbourne (to whom I am indebted for an examination of the outer layer) reports that the fragments tested consist of calcium and magnesium phosphates, with a possible admixture of triple phosphates. The specimen has been presented to the museum of the Medical School of the University of Melbourne.

Mr. H. Littlewood, in THE LANCET of May 11th, 1907, p. 1315, gives a list of the largest calculi successfully removed up to that date. The largest weighed nearly 344 ounces and measured 6 inches by 4 inches diameter. was removed by Mr. H. M. N. Milton 1 at Cairo by abdominal section from an Egyptian fellah, aged about 60 years, who survived about two and a half months. During part of this time he was sufficiently recovered to go out in the hospital garden, but he eventually sank and died in the hospital from kidney disease, the power of expulsion having never been regained by the bladder, which was drained by a fistula. The second on the list was one of 24½ ounces removed by Sir Thomas Smith² at St Bartholomew's Hospital, London; this stone measured 13 inches by 92 inches in its longest and shortest circumferences respectively. The patient made a complete recovery.

In January of last year Dr. Owen Richards of Cairo successfully removed from the bladder of an Egyptian fellah, aged about 40 years, a stone weighing 32 ounces and measuring 4½ by 3½ by 2½ inches in its various diameters. The operator first endeavoured to crush the calculus with a lithotrite, but finding this impossible he removed it by fragmentation through incisions in the perineal and suprapubic regions. The patient left the hospital before the perineal wound was quite closed, but it is reported that when seen three and three-quarter months after the operation this was completely healed and that he had gained 12 pounds in weight and seemed in excellent health and spirits. His only disability was that when he walked about some urine dripped from his penis, and he had contrived to sling a little tin under it to keep himself dry. When he lay down he could hold his urine and pass it voluntarily.

This is the only successful case of which I can find any record in which a calculus of over 26 ounces has been removed since Mr. Littlewood's list was published. It would appear, therefore, that with the exception of the two Egyptian specimens removed by Mr. Milton and Dr. Richards respectively, the stone which forms the subject of these notes is the largest yet successfully removed of which particulars have been published.

With regard to the choice of operation, three methods present themselves—litholapaxy, suprapubic lithotomy, and laparotomy. In this case the calculus was so large and the patient so frail that I believe litholapaxy was out of the question, while the accompanying cystitis was so intense that any procedure involving the opening of the peritoneal cavity would appear to be admissible only as a last resort. Suprapubic lithotomy with fragmentation, therefore, was selected as the operation most suitable, this appearing to impose the smallest tax upon the patient's vitality. while at the same time providing a means of irrigating the bladder which might be expected to be of service in clearing up the cystitis. Fragmentation I expected to be able to effect by means of the lithotrite, but the largest instrument usually employed was absolutely useless. Dr. Richards in his case of a stone of 32 ounces (a male patient) used with marked success an osteotome and hammer, and very aptly points out that these large calculi can frequently be broken with light, sharp taps, while their inertia militates against the danger of injury to adjacent viscera, and one cannot help feeling that in the majority of cases such is the best means of dealing with them. In my own case this method was considered, but in the female the risk of damage to the pelvic organs from jarring appeared to me to be sufficiently great to make it desirable to remove the stone, if possible, by some other

In conclusion, I should like to express my indebtedness to Mr. Honman and Dr. Nattrass for their very able support during the operation.

Melbourne.

THE PLEA OF LUNACY IN THE CRIMINAL COURTS OF SCOTLAND.

BY JOHN GLAISTER, M.D. GLASG., F.R.S. EDIN., PROFESSOR OF FORENSIC MEDICINE AND PUBLIC HEALTH IN THE UNIVERSITY OF GLASGOW; EX-PRESIDENT OF THE FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW; MEDICO-LEGAL EXAMINER IN CROWN CASES, ETC.

A PLEA of lunacy in the case of a prisoner charged with a serious crime or grave criminal offence arouses always several important issues not only from the medical but also from the legal point of view. From the medical point of view it is not unimportant whether the plea is in bar of trial or in bar of sentence, and whether the plea is put forward by the Crown or by counsel for the accused. Except in certain cases in which the insanity of a prisoner is obvious there are not infrequently exhibited differences of opinion among medical witnesses, even among expert alienists, as to the existence of insanity, or at least of such departure from normal average mental ability as, in the former case, would disable or prevent a prisoner to instruct his defence and thereby prevent a trial, and in the latter case would prevent sentence being pronounced by reason of insanity existing at the time of commission of the crime charged. In the latter case, solution of the question is not rendered easier by the circumstance that the examination of the prisoner by the medical witnesses is always post fasto, may have to be conducted some time after the time of commission, and in these circumstances the insanity has to be inferred from the nature of the act itself, together with the history and conduct of the prisoner precedent and subsequent to the commission of the act. It is necessary for the medical witnesses in all such cases not only to form an opinion regarding the insanity of the prisoner, to state upon what grounds such opinion is founded, but also to advise the court as to whether the prisoner's mental state is such as prevents him from giving intelligent instructions for his defence, or whether at the time the crime was committed the prisoner knew the nature and quality of his act, or, if he did know, that he did not know he was doing what is wrong. All these questions involve grave and anxious consideration. While it is the duty of the court or jury to determine the question of responsibility, the court expects that the medical witnesses will be prepared to offer evidence which will enable them to so determine.

This opens up the whole vexed question as to the determination of responsibility in the opinion of the witnessesa question regarding which it cannot be pretended there exists any broad line of agreement among the members of our profession, even among alienists. There are some who are of opinion that the act of any person which destroys the life of another by directly applied violence is an insane act, that for the time being such person has lost all power of self-control, and ought, therefore, to be deemed irresponsible. Such a view, carried to its logical conclusion, would lead to the abolition of punishment for what is deemed by the law to be crime. and to the abolition of our present conception of what crime is, in respect that it pre-supposes the absence of selfcontrol during all such acts. Such a view, however, cannot be sustained in reason. Doubtless, persons vary considerably in their powers of self-control, just as they vary in their mental capability, but the law in theory and in practice pre-supposes that all persons should be able to exercise that measure of self-control as would prevent them by any unlawful act placing in jeopardy or putting an end to the life of another, unless there be such a defect or deficiency or absence of power of control, through disease of mind or otherwise, as to render them unfit to resist their impulses to destruction. Alienists differ amongst themselves regarding this normal average measure of self-control. No hard-andfast line can be drawn between two or more individuals, on one side of which it may be said that one was entirely capable of exercising control and was therefore responsible for his act, and on the other side of which another was entirely incapable of so exercising control and was therefore wholly irresponsible. It would be difficult for the law to decide upon fine-drawn distinctions as to full responsibility and complete irresponsibility; it can only be expected to decide regarding the average condition of mankind in that regard. In short, if the thing or entity which we call crime

THE LANCET, Sept. 16th, 1893, p. 687.
 THE LANCET, August 7th, 1886, p. 246.
 THE LANCET, July 25th, 1908, p. 231.

be but a manifestation of disordered mental function, then we ought to cease calling it crime, and instead of in prisons we should have to incarcerate in asylums those But the law has not reached who commit such acts. such conclusion, and is not likely to do so; and, it may be added, neither has the medical profession generally nor the intelligent public. So long as evil motives actuate mankind, and so long as jealousy, covetousness, revenge, and other similar qualities exist, it must be held that men will commit crimes, even of the most brutal and revolting character.

Moreover, there are some who aver that they see in the character of a crime itself good ground for considering that it was the act of an insane person. We have heard the opinion expressed in court of the insanity of an accused person that it was founded on the brutal nature of the act committed. This, it appears to us, does not in itself form a safe ground for such conclusion. It may, indeed, happen that the nature of the crime does indicate prima facie the existence of disordered mind in the perpetrator, but such a view requires to be buttressed by other evidence, such as may be found in the prisoner himself, in his past history or present

The usual procedure in a case in which insanity is placed in bar of trial and where both prosecution and defence are agreed is as follows. The accused person being brought to the bar, and before empannelling a jury, counsel for the accused or for the Crown, as the case may be, most commonly the former, calls witnesses to speak to the mental state of the accused and to his ability to instruct counsel for his defence. If the court is satisfied that the evidence proves such mental disability as renders the accused incapable of instructing his defence, the court will pronounce accordingly, and will order accused to be confined until His Majesty's pleasure is known. Where insanity is pleaded in bar of sentence the procedure is Such a plea involves the view that accused was different. of unsound mind at the time he committed the act, although he is not insane now. After the accused is placed at the bar he is asked to plead to the charge read against him. pleads not guilty. A jury is then empannelled and sworn to truly try him, and evidence of the commission of the crime is adduced in the usual manner. Counsel for the accused will likely either cross-examine witnesses adduced by the Crown in order to discover evidence of the accused's mental condition before the commission of the crime, at the time of arrest, and thereafter, or he may, in addition, call medical evidence to show that at the time the act was committed the accused was not of sound mind. The judge in his summing of the facts to the jury will not only indicate the bearing and value of the evidence led regarding the mental state of the accused, but will point out to the jury what questions they are bound to answer. The jury may return a verdict of guilty as libelled, a verdict of culpable homicide where the original charge was one of murder, or it may return a verdict that the accused committed the act but was insane at the time of commission. If the last-named verdict be returned the court will order the accused to be confined until the Royal pleasure is known.

Where insanity is pleaded in bar of trial the theory of the law is that if it be proved that the prisoner before and at the time of trial is incapable of instructing his defence because of mental disability, or because of his inability to communicate with or be communicated with by others by reason of physical disability, he is insane, and therefore cannot be tried. The two following cases illustrate disability of the latter kind.

In 1897 a man named Harris was charged before Mr. Justice Darling and a jury at the Central Criminal Court, London, with the crime of murdering his wife. After killing his victim he attempted to commit suicide by cutting his throat. The effect of his self-inflicted wound was to destroy his vocal cords, so that he was unable to speak. Neither could he read nor write. Hence he was unable to instruct his defence. The law of England is that punishment cannot follow a criminal act (1) where the accused is found to be insane; (2) or is mute from defective organisation; (3) or where the accused cannot plead from want of an adequate interpreter or an interpreter of any kind. This man being unable to speak, to read, or to write, was to all intents and purposes mute, and thereby was unable to instruct his defence. Mr. Justice Darling put certain questions to the

jury, in answer to which they found (1) that the prisoner could plead to the indictment; (2) that he was sane; (3) that he was not then capable of instructing his defence; and (4) that the cause of his disability was the result of his own unlawful act. The judge thereupon asked the prisoner to plead, whereupon he whispered "Not," and the judge ordered the trial to be adjourned till the next assizes. Harris was brought up for trial on Jan. 12th, 1898, before Mr. Justice Channell and a jury, and at the conclusion of the evidence was found guilty by the jury, who also found that he was responsible for his actions up to the time he committed the crime. The jury added a strong recommendation He was sentenced to death.1 to mercy.

The following is also an unusual case, viz.: The King v. The Governor of His Majesty's Prison at Stafford, En parte

A prisoner, who was totally deaf and could neither read nor write, was arraigned for a felony. Upon being arraigned, he stood mute, and a jury, duly empannelled and sworn for the purpose, found that he was mute by the visitation of God. The jury were sworn again to try whether he was capable of pleading to the indictment, and they found that he was incapable of pleading and taking his trial upon the indictment and of understanding and following the proceedings by reason of his inability to communicate with and be communicated with by others. Upon this finding, the judge, acting under Section 2 of the Criminal Lunatics Act, 1800, ordered him to be kept in custody until His Majesty's pleasure should be known. Held: That the finding amounted to a finding that the prisoner was insane within the meaning of the Act and that the order was properly made.²

The whole question from the legal side has been tersely and clearly put as follows :-

and clearly put as follows:—

In a strictly legal sense there is no insane criminal. Concode insanity, and the homicidal act is not criminal. The act of the insane, which in the sane would be criminal, lacks every element of crime. A sane man, who has committed crime, may thus become insane, either before or after conviction for the crime. He may be rightfully called an insane criminal. If the insanity develops before the trial, the law would suspend his trial while the insanity continued. If the insanity came after conviction, he should be treated as an insane man, not as a criminal. The medical mind frequently views the question of insanity as one of responsibility only. To the legal mind, insanity conceded, responsibility ends. If a man is clearly insane, he is not a criminal, even though "he has within him a tendency sufficiently strong to cause him to commit offences against both person and property." He needs care, and the State has the right, and it is its duty, to protect him from the consequences of his own mental condition. It is a question of fact, usually for the jury—is the man, or was the man, insane at the time the act was committed? If the jury says by its verdict he was insane, then the court sends him to an asylum for the treatment of the insane. If the verdict is that the prisoner is guilty, the effect of that verdict is that he was not insane, and the court sends him to prison. If the jury err, and pronounce an insane man guilty, he comes into prison by the side of the criminal who after conviction becomes insane. But there is, in fact, a wide distinction between them—the one is absolutely innocent of crime, because he was insane at the time of the act, and he is in no sense a criminal in fact. The other, who is a criminal in the eye of the law, has a "disturbed intervals."

The following cases, of which brief notes are given, strict in the send of the criminal who have lucid intervals.

The following cases, of which brief notes are given, tried before the Scottish Criminal Courts, have points of individual interest worthy of note and consideration.

interest worthy of note and consideration.

1. At the High Court of Justiciary held at Glasgow, September, 1902, a man was indicted on a charge of murder, he having shot another man in the throat with a revolver loaded with ball cartridge and killed him. Having made the post-mortem examination of the body of the deceased man we were in court during the trial and heard the proceedings. On the indictment was the usual list of witnesses. When the case was called the late Lord Young, who was on the bench, asked the Advocate-depute why there were so many medical witnesses in the case. The reply was that the Crown thought it desirable to ask two doctors whose names were on the list to examine the accused with regard to his mental condition lest a plea of insanity might be set for the accused if he was to found on a plea of insanity. To this counsel replied in the negative. Whereupon his lordship said that the two dectors in question need not be called, and might, therefore, be dismissed. The facts of the shooting were clearly proved. It was given in evidence that a quarrel had arisen between accused and deceased, that immediately thereafter accused journeyed into Glasgow, bought a revolver, and returned to the shoot of deceased and there shot deceased while sitting at a desk. Not a word was said by prisoner's counsel during the trial, either in cross-examination of witnesses or in his speech to the jury, which even hinted that the prisoner was of unsound mind. Lord Young, however, in addressing the jury, suggested to them that the man besonce of 25 minutes, the jury returned a verifict that the accused had committed the act with which he was charged, but that he was during His Majesty's pleasure.

Probably there was no one in court more surprised at the

Probably there was no one in court more surprised at the verdict than the prisoner himself.

2. At the High Court of Justiciary at Bdinburgh, on Sept. 18th, 1882, a man was tried before the Lord Justice-General and a jury on a change of

Session Papers, 1896.

having murdered one of the lecturers of Surgeons' Hall and another

having murdered one of the lecturers of Surgeons' Hall and another man, by shooting them. Counsel for the defence contended that the prisoner was insane at the time of commission of the act, but he contented himself with leading that view by cross-examination of witnesses and did not call expert medical evidence. The Solicitor-General, who conducted the case for the Crown, in his address to the jury said that in view of the defence set up for the accused there were three possible verdicts before them—viz., guitty of murder, guitty of culpable homicide, or they might acquit the prisoner on the ground of insanity. Counsel for the prisoner argued that prisoner was insane, but if he had falled to prove that to their satisfaction he suggested that they should find that the prisoner had no felonious intent in his act, that he was not guilty of murder but of culpable homicide.

The Lord Justice-General in summing the case dealt with the alleged mental defect of the prisoner at the time he committed the act. He remarked that it had been said on prisoner's behalf that when he did these acts he was not morally responsible for what he was doing. His Lordahip did not understand that it was disputed that the prisoner was aware that he was shooting the men to death. The jury would probably think he was aware, and, if so, the question they would have to decide was: What was the effect of the mental alienation which was said to have existed, and which, it seemed to him from the evidence, did undoubtedly exist to a very considerable extent. He would say, however, that the mere fact of a person suffering from a certain degree of mental slienation or mental delusion would not necessarily exempt from criminal responsibility, and in order to exempt from liability to punishment insanity must amount to such an alienation of reason that the accused did not know the nature and quality, was in such a state of mind that he was not aware of what he was one awing the law, he was responsible. Unless they thought it was established that the enjoyed.

The jury returned a verdict of culpable homicide by a majority of

The jury returned a verdict of culpable homicide by a majority of 1, and the prisoner was sentenced to penal servitude for life.

3. Cumnock polsoning case. A man was brought before the same court at Edinburgh in March, 1907, on the charge that on Nov. 19th, 1906, he sent by post to W. L. in Old Cumnock a cake of shortbread having a covering or layer of icing adherent thereto, with which icing he had previously mixed a quantity of strychnine, his intention in so sending the cake being to poison the said W. L., and said cake having been delivered to the said W. L., a portion of said cake and icing was esten on Nov. 23rd by the housekeeper to the said W. L., in consequence of which she died, and that he did thus poison her and did murder her.

sending the cake being to poison the said W. L., and said cake and cing was eaten on Nov. 23rd by the housekeeper to the said W. L., in consequence of which she died, and that he did thus poison her and did murder her.

The Solicitor-General, who prosecuted, put forward the plea that accused was insane and incapable of pleading. This was opposed by counsel for the accused, who asked that a plea of not guilty should be accepted. On account of the unusual course which was proposed by the Crown, the special plea was heard before several judges. The Solicitor-General said that the ordinary procedure had been followed in the case. The accused had emitted a declaration on Nov. 29th before the Sheriff, and he was committed for trial on Dec. 8th. After the latter date, it came to the knowledge of the Public Prosecutor that accused was probably insane. Accused was thereupon placed under medical supervision, and reports from skilled medical men were obtained that accused was insane. At the pleading diet held in Ayr on March 8th, 1907, a medical certificate having been produced to that effect, the Sheriff-substitute did not call upon accused to plead. Accused was in the same condition now as he was then. The statutory procedure came under Section 87 of the Lunacy (Scot) Act of 1857 (20 & 21 Vict. cap. 71), which enacted that where any prisoner charged under any indictment for the commission of any crime was found to be insane, such prisoner could not be charged under such indictment; but nothing was said in that section whence the information of insanity might come to the court. If there was a doubt as to the analty of a prisoner, then an inquiry was to be held. While no reference was made in the Act as to the particular mode by which the inquiry was to be prosecuted, the established practice of the High Court. followed for more than a century, was that the investigation should be conducted by a judge without the intervention of a jury. The same section further enacted the procedure to be followed where, after the trial h

upon to plead at the pleading diet either directly or through a law agent, the reason urged for that being that he was insane. Coursel called the attention of the court to the danger of an exparts inquiry as to mental ability, as any law-abiding citizen might be arrested for a crime committed in any part of the kingdom, and in answer to his plea of innocence the Crown might, as now, plead his mental unsoundness. It seemed to him that the procedure in this case was ruled by the Criminal Procedure Act, 1887, Section 24, which made provision for the service of an indictment on accused persons, by Section 25, which provided for two diets of court, and by Section 29, which regulated the procedure to be followed at the first diet. The Crown here had adopted the two first-named sections by serving an indictment and by calling

It seemed to him that the procedure in this case was ruled by the Strinical Procedure Act, 1887, Section 23, which made provision for the service of an indictment on acoused persons, by Section 25, which provided for two diets of court, and by Section 25, which provided for two diets of court, and by Section 25, which provided to two diets of the procedure to be followed at the first diet. The Crown here had adopted the two first-named sections by serving an indictment and by calling upon accused to appear at two diets, but had failed to obtemper the procedure laid down in the last-named section in respect that accused had not been allowed to plead. His contention was that, having a service of the procedure of the procedure of Section 29. He (counsel) had been instructed by the accused to maintain his innocence, his instructions having been received direct from the accused, these being intelligent instructions and such as he might receive from a sane man. He therefore contended that the procedure at the pleading diet at Ayr was incompetent and irregular in respect that accused had not been permitted to plead, though willing, that the first diet being incompetent, there could be no trial, and that the court should discharge the accused, since he could not be tried under the Criminal Procedure Act, 1887. The Lord Justice-General pointed out that the Sheriff wasleft in the same position as the High Court now was under the Act; and Lord McLaren said that a prisoner suffered no prejudice whatever by not being asked to plead in the Sheriff Court. Since it was the law that whether a man pled guilty or not guilty in the Sheriff Court he could be asked, indeed was asked, in this court to plead again, and could withdraw or could modify the terms of a previous plea.

The court retired for consultation, and, on returning, the Lord Justice-General—Lord Dunedin—gave the judgment. He said it was clear from the cases cited that from a very early period it had been the prisoner should or should not be asked to plead. He agreed

stantial. Neither was there any motive disclosed for accused's alleged act.

In addressing the jury on behalf of the Crown at the conclusion of the evidence, the Solicitor-General said that the jury might have at least three questions to consider, but they might have only one. The first question was: Whether or not the prisoner was now insane. If they found the prisoner to be now insane, then they had no further questions to consider; they would not acquit him, and they would not convict him: they would simply find him insane, and he would be confined and be taken care of. His contention from the evidence was that the prisoner was now and had been suffering from chronic epileptic insanity. If, however, the jury took the view that the prisoner was sane, they would then have to consider whether or not he was guilty of the crime with which he was charged. No witness had seen prisoner despatch the parcel, and this was a case of circumstantial evidence—they must rely on a chain of facts all pointing in one direction or another. In his opinion that chain pointed unmistakably and unerringly to the prisoner as the man who despatched the parcel.

Counsel for accused submitted that the course adopted by the Crown was a weak and cowardly course. What right had the Crown to indict a fellow-citizen of a crime so helmous and detain him is gool for a period of 110 days, to indict him after he has been detained for 80 days, and then at the end of a three days 'trial say to them (the jury) that it did not matter whether he was guilty or innocent, and ask them to take upon themselves the responsibility of treating the prisoner as though he were guilty, and of pronouncing against him a verdict that he was in that state that he could not instruct counsel, and, further, that he was not entitled to have his innocence proclaimed? He as counsel for the prisoner had had the advantage which the jury had not had of

interviewing his client, and he had received from him the clearest and

interriewing his client, and he had roceived from him the clearest and myst specific instructions in connealon with the defence of his case. His contention was that the case of the Crown from beginning to end myst specific instructions in connealon with the defence of his case. His contention was that the case of the Crown from beginning to end secured and the writing with the sending of the cake. But in respect to the case of the case which indicated that more than one person had been engaged in the sending of the cake. But in respect to the case of the case of the person had been engaged in the son and on the label of the parcel political in the other day of Nov. 18th had been completely on the card of greeting from the day of Nov. 18th had been completely his having despatched any cake or of having mixed with it any cling, the ingredients of which contained the strychning and that it was an absolute and entire impossibility that the prisoner could have rarvial in Glasgow and his reaching the groes's shop. Moreover, there was no motive of the slightest sort or description suggested for the accounds acting as he had boon charged. He therefore implored them to the consequence of the case of the control of the case of the c

it seemed to him that the position of counsel was becoming reversed. He should have thought that prisoner's counsel would have tried to get him off by pleading that accused was insane, but instead of that counsel was maintaining that accused was sane and was, therefore, responsible for his actions. On the other hand, the Advocate-Depute, who prosecuted, suggested that the evidence might make out accused to be insane. Prisoner's counsel said that he had got notice that the Crown was to oppose a plea from the prisoner, but no notice had been taken by the Advocate-Depute of accused's alleged mental condition. His instructions from the prisoner were that before everything he was to be held sane by the jury. The Advocate-Depute had now stepped in with a new method of criminal procedure. The attitude of accused was that while he deliberately shot at the doctor it was for the purpose of bringing his case before the public, that while he did shoot he was very careful not to kill but merely to hurt the doctor as slightly as he could with the weapon he employed. Lord McLaren then saked: Should not accused have pleaded guilty? To this counsel replied that he had been given notice by the Crown that the question the Crown was to raise before the jury was, Whether the man was sane or not? The court was to understand that instead of defending accused on the ground of insanity, he made no such plea, but that accused was responsible for his actions. The Advocate-Depute said that the view of the Crown was that prisoner was a dangerous subject, and that it was an appropriate method to deal with him as a criminal lunatic, and that steps should be taken so that he might never get out of confinement again.

Two lunacy experts averred that prisoner was subject to delusional

again.

Two lunacy experts averred that prisoner was subject to delusional insanity, one of them even going the length of saying that accused had been insane since the beginning of 1903 and had continued so ever been insane since the beginning of 1903 and had continued so ever been insane since the beginning of 1903 and had continued so ever been insane since the beginning of 1903 and had continued so ever been insane since the beginning of 1903 and had continued so ever been insane since the beginning of the b

Since. Evidence for the prisoner was adduced by the prison surgeon and the assistant surgeon, under whose care accused had been while in prison, as well as by a police surgeon who also examined him, by two sons, by other relatives of prisoner, and by the prisoner himself. The medical witnesses said the result of their examinations of accused was that they Bytience for the prisoner was adduced by the prison surgeon and the assistant surgeon, under whose care accused had been whi, ein prison, as well as by a police surgeon who also examined him, by two sons, by other relatives of prisoner, and by the prisoner himself. The medical witnesses said the result of their examinations of accused was that they did not believe accused to be suffering from insane delusions. There might be what might be called delusions, but they were seed on factoring the surgeon of the surg

against the law, and had decided to take the punishment of his crime rather than be sent to a lunatic asylum. As prisoner had been found by the jury to have been of sound mind not only at present but at the time the orime was committed the must take it that accused forease as a case of sudden assault committed the must take it that accused forease as a case of sudden assault committed in the most take it that accused forease to receive the present of the property of the case of sudden assault committed to the statement that he did not mean to kill the practitioner, but as to be statement that he did not everyone knew that if one fired a shot, and espoting him bodily harm, everyone knew that if one fired a shot, and espoting him bodily harm, everyone knew that if one fired a shot, and espoting him bodily harm, everyone knew that if one fired a shot, and espoting him bodily harm, everyone knew that if one fired a shot, and espoting him bodily harm, everyone knew that if one fired a shot, and espoting him bodily harm, everyone knew that if one fired a shot, and espoting him bodily harm, everyone knew that if one fired a shot, and espoting him bodily harm, everyone knew that if one fired a shot, and espoting him bodily harm, everyone knew that if one fired a shot, and espoting him bodily harm, accused the take of the case exceed his analytic and the facts of the case exceed by a shot in the facts of the case exceed had considered his analytic had been confined in Perth Lunacy Prison, and having recovered his sanity had been liberated, but was immediately thereafter arrested. Accused pled not guilty to the charge, a special defence on his cehalf having been put in that accused was insane at the time when the crime was said to have been committed. Evidence was led respecting the circumstances of the shooting. A medical witness stated that before the commission of the deceased had consulted him about arenteal poisoning, and said to him that his relatives were promited to the crime him to the said and the fact the had

directed the jury that there was no room for the inea that the accused was in the eye of the law and in the present state of legal opinion not fully responsible for the act.

The jury unanimously found the prisoner guilty of murder. He was sentenced to death without any recommendation to mercy. The condemned man was taken to the prison of Ayr, where, according to the terms of the sentence, he was to be executed. There was no public petition for a reprieve; on the contrary, local opinion was in favour of the verdict. Preparations were in progress for carrying out the execution, the scaffold had been erected, and the public executioner was in the town. In some way, however, not publicly known, the Secretary for Scotland sent a commission of mental experts to Ayr 15 days after the trial, and six days before the date fixed for execution, with a view to further examination of the condemned man, and to report. What these experts reported is not known, but it is a rea-onable inference that from their examinations they did not find evidence to warrant them reporting that the convicted man was insane, because a respite only followed, which arrived 14 hours before the time fixed for execution, a respite not for the purpose of sending the man to a lunatic asylum, but, as events proved, for the purpose of sending him to penal servitude for life.

The foregoing cases show sufficient variations in the incidence of insanity in relation to the commission of crime and the practice of the law as are likely ever to come under the consideration of the Scottish Criminal Courts. But before discussing their details it will, perhaps, be well if the statutory enactments regarding procedure in cases in which insanity is pled in bar of trial or in bar of sentence should first be considered. These are to be found in the Lunacy (Scotland) Act, 1857 (20 & 21 Vict., cap. 71), ss. 87. 88. and 89, and in the Lunacy (Scotland) Act, 1862 (25 & 26 Vict., cap. 54), ss. 15 and 19.

Section 87 of the Act of 1857 reads as follows :-

Where any person charged under any indictment or criminal libel with the commission of any crime shall be found insane, so that such person cannot be tried upon such indictment, or if upon the trial of any person so indicted such person charged with such indictment or criminal libel shall appear to the jury to be insane, the court before

whom such person shall be brought to be tried as aforesaid shall direct a finding to that effect to be recorded, and thereupon such court shall order such person to be kept in strict custody until His Majesty's pleasure shall be known; and it shall be lawful for His Majesty to give such order for the safe custody of such person so found insane during his pleasure in such place and in such manner as to His Majesty shall seem fit.

Section 88 says :--

Section 88 says:—

In all cases where it shall be given in evidence upon the trial of any person charged under any indictment or criminal libel with committing any crime or offence that such person was insane at the time of committing such crime or offence, and such person shall be acquitted, the jury shall be required to find specially whether such person was insane at the time of the committing such crime or offence, and to declare whether such person was acquitted by them on account of such insanity; and if they shall so find and declare, the court before whom such trial shall be had shall order such person to be kept in strict custody in such place and in such manner as to the court shall seme fit, until His Majesty's pleasure shall be known; and it shall be lawful for His Majesty to give such order - [&c., as in previous section].

Section 80 provides for the case of a prisoner who exhibits

Section 89 provides for the case of a prisoner who exhibits insanity when in confinement as a prisoner under any sentence or under any charge of any crime or offence, or under any civil process. In such case the sheriff shall inquire, with the aid of two medical persons, as to the insanity of such prisoner, and if it shall be certified by such sheriff and such medical persons that such prisoner is insane, it shall be lawful for one of His Majesty's Principal Secretaries of State, upon receipt of such certificate, to direct by warrant under his hand that such person shall be removed to an asylum as the said Secretary of State may judge proper and appoint; and every prisoner so removed under this Act from prison to an asylum by reason of his insanity shall remain in confinement in such asylum until it shall be duly certified to one of His Majesty's Principal Secretaries of State by two medical persons that such person has become of sound mind, whereupon the said Secretary of State is hereby authorised, if such person shall remain subject to be confined in custody, to issue to the superintendent of such asylum directing that such person shall be removed back from thence to the prison or other place of confinement from whence he shall have been taken, or, if the period of confinement of such person shall have expired, that he shall be discharged.

Section 15 of the Act of 1862, which repealed Section 85 of the Act of 1857, provides that when the lunatic shall have been apprehended, charged with assault or other offence inferring danger to the lieges, or when any lunatic shall be found in a state threatening danger to the lieges or in a state offensive to public decency, it shall be lawful for the sheriff of the county in which such lunatic may have been apprehended or found, upon application of the procuratorfiscal or inspector of poor or other person, accompanied by a certificate from a medical person bearing that the lunatic is in a state offensive or threatening to be offensive to public decency, forthwith to commit such lunatic to some place of safe custody. Thereafter the sheriff shall give public notice that he proposes on a date to be named in such notice to inquire into the condition of such lunatic. Section 19 deals with the procedure to be followed in the case of any convict or person confined in the General Prison at Perth who at any time within 60 days of the expiration of his sentence is certified to be insane, and for the treatment of such convict or person, if thought fit, in an asylum rather than in prison.

Having briefly glanced at the law on the subject of lunacy in relation to criminal matters, I propose now to deal with the cases already discussed. It will be observed that each of these cases bears some individual peculiarity which differentiates it from the others.

In the first case the peculiarity consists in the fact that although there was no plea of insanity, nor indeed any insanity founded upon, the judge was the first and only person to suggest in his directions to the jury in anity in the prisoner. This appeared to be at the time, as it really was, a most unusual procedure. While it is unquestionably the duty and function of a judge to see that every prisoner has a fair trial and that nothing is lost sight of which may be put in his favour, it is the fi st case within my knowledge where, a prisoner being defended by senior and junior counsel, and insanity has not been any part of the defence, the judge interposed his suggestions of the insanity, and therefore the irresponsibility of the prisoner. It would almost seem as if the judge had believed that the prisoner had not been efficiently defended.

The second case differs from the first. Here there was evidence indicative of some measure of mental unsoundness:

but although the judge said to the jury that the evidence led pointed to the fact that the prisoner had got into a condition of ill-health, mental and physical, different from that which he had formerly enjoyed, the jury found the prisoner guilty of culpable homicide by a majority of one.

The third case seems at first sight to be somewhat extraordinary. One cannot help thinking that the proper method of reaching the true conclusion in this case had not been adopted, while at the same time it is not easy to suggest a Doubtless the element of unsatisfactoriness consists in the fact that an accused man whose sanity and fitness to plead had been challenged at the beginning of the case, and who had been found to be insane at its finish, had been permitted to plead, and also, perhaps, because after being permitted to plead and after all the evidence had been led on both sides, no finding was required of the jury as to whether or not the accused committed the act charged against him. The case is further noteworthy in that it signalised a notable departure from the practice of the courts in like cases. For the previous century, when a plea in bar of trial on the ground of insanity had been put in, the practice was for the court, without the aid of a jury, to determine the issue, irrespective of whether the plea had been put in by the defence or the question had been raised by the prosecutor. In this case, it will be remembered, the issue was raised by the The last previous case in which similar circumstances obtained was the somewhat famous case of Alexander Robertson, alias "Dundonnachie," which came before the High Court of Justiciary at Edinburgh on March 30th, 1891. The question of the sanity of Robertson having been raised before the court, Lord Justice Clerk Macdonald (Lord Kingsburgh) himself determined the issue without the aid of a jury. In all the cases in which I have been engaged where the plea of insanity in bar of trial was raised by the defence, the issue was always determined by a judge alone. According to the same authority, "Where such a plea is tendered, proof in regard to it may be taken by the judge without impannelling a jury. If present insanity is proved, the court find that the accused cannot be tried, and order him to be confined until the Royal pleasure be known. Although no question as to sanity be raised by the accused, the prosecutor may raise the question, and the court, if they shall see cause, will, ex proprio motu, investigate whether the accused be a fit subject for trial or not ""

It is not unlikely that the procedure in the third case would have been in accordance with former practice had the question of the man's insanity not been strenuously contested by his counsel, who, as events showed, contented himself merely with a general denial of the averment of insanity and did not adduce any medical evidence to rebut that of the Crown. It seems clear that had the plea in bar of trial been determined by the court without a jury there could have been no trial. As the facts are, however, we behold a prisoner whose sanity is disputed, and who is found insane at the end of his trial, being permitted to tender a plea—a circumstance which could not have happened had the issue of insanity been determined first by the court. Apart altogether from the question of the sanity of the accused, and solely on the evidence led to connect him with the commission of the crime charged against the light of the evidence which was led, that any jury, supposing they had had the chance of returning a verdict, could have returned one of guilty as libelled. The only connecting link, if such it may be called, was the alleged similarity of the handwriting, and it is difficult to imagine, in view of the case of Adolf Beck, which doubtless would have been brought before the notice of the court, that the jury would have convicted a man for murder on mere identity of handwriting. It is, perhaps, true that the accused here did not suffer any substantial harm from the course adopted, because by their verdict the jury did not pronounce on the charge itself; at the same time, owing to the fact that the prisoner was allowed to plead and the trial to proceed, and evidence regarding the possible commission of the crime was adduced. the absence of a finding by the jury on the merits left the case undetermined and a certain stigma to remain on the character of the accused in the minds of the general public. It seems to me that the same effect, so far as the accused was concerned, would have practically followed had the questions

submitted to the jury for answer been put in a different order. One difference probably would have resulted-vis., that if the jury had answered the second question first, and if the jury had returned a verdict of not guilty or not proven, and if they had then answered the first question in the affirmative, seeing that the issue had been raised in the commencement of the case, the destination of the accused would probably not have been a criminal lunatic asylum but a private asylum, on his friends undertaking to the satisfaction of the court that such would be done. It will be noted that the jury had all the facts before them on which to found a verdict on the merits, but they were precluded from that course by finding a verdict that the accused was now insane. Had the questions been put in the following order such a result as has been indicated would have been possible, viz.:—(1) Did the prisoner send this poisoned cake? (2) Is the prisoner now insane? and (3) If not now insane, was he sane or insane when he did it? This last question, of course, could only require an answer if the jury found that the act had been committed by the prisoner. But putting the questions in the order in which they were presented to the jury by the court, an answer in the affirmative to the first stopped the proceedings, since that answer involved a finding that the prisoner was unable to instruct a defence, and, therefore, could not plead. But if in the light of the evidence adduced we are warranted in the assumption that the jury could not have returned an affirmative answer to the question, Did he send the poisoned cake? we cannot assume that it would be good law to then ask the jury to answer the question, Was the prisoner insane now?

З

Had the case occurred under English procedure, the problem, I think, would have been solved more easily and more satisfactorily. On the question of the insanity of the accused being raised a jury would have been empannelled and sworn to determine the issue whether or not the accused was fit to plead. If a negative answer was returned by the jury, the accused would then be ordered into confinement to await the Royal pleasure. But if an affirmative answer were given, the jury would again be sworn to try the accused, who would be called upon to plead to the indictment, and the trial would proceed, and the jury would return a verdict. I do not pretend to be able to say, now that the former practice of the Scottish courts has been changed where the question of the insanity of a prisoner is raised by the Crown, whether the powers contained in the Lunacy (Scotland) Acts permit the question of the fitness of such a prisoner to plead to be put as a preliminary inquiry before a jury. It is quite clear, however, that a jury empannelled to try such an accused person as Brown, whose sanity is challenged by the Crown, but which challenge is resisted by the accused, can determine the issue—whether or not the accused is now sane. The decision of the bench of judges appears to us to have been founded on Section 87 of the Act of 1857, which we have already quoted. It will therein be seen that "where any person charged under any indictment or criminal libel with the commission of any crime shall be found insane, so that the person cannot be tried upon such indictment the court before whom such person shall be brought to be tried as aforesaid shall direct a finding to that effect to be recorded, and thereupon such court shall order such person to be kept in strict custody until His Majesty's pleasure shall be known"; but the section goes on to say, "or if upon the trial of any person so indicted such person charged with such indictment or criminal libel shall appear to the jury to be insane" the court shall direct a finding to that effect to be recorded, &c. The reading of the section seems to indicate two alternative methods of procedure, the first not being a trial in respect that the accused is not called upon to plead because of his being found to be insane, the second, however, being a trial, the accused having pleaded and a jury having been empannelled to try Section 88 deals with the case of any prisoner where it shall be given in evidence upon the trial that such person was insane at the time of committing the crime or offence with which he is charged. It will be seen in the questions put to the jury by the Lord Justice-General that the procedure in this section was also included. Reviewing the whole procedure in this case one cannot help coming to the conclusion that where a man charged, as this man was, with so dastardly a crime, is not called upon to plead at the pleading diet because of his having been certified to be of unsound mind and unable to instruct his defence, and whose sanity was

^{4 3} White, 6.
5 Macdonald: Criminal Law of Scotland, third edition, p. 431.

questioned in the same way precedent to his trial, he should either have been subjected to an inquiry as to his fitness to plead, or, having been allowed to plead, that the jury ought to have been called upon to say whether or not from the evidence he committed the act charged against him.

The fourth case which we have cited is exactly similar to the case just discussed up to and including the point of procedure where the accused is allowed to plead. It differs, however, from it in the following particulars—(1) there was no doubt that the accused committed the act charged; (2) that accused had already been incarcerated in an asylum for a few months some time previously, but had been discharged therefrom on an action of liberation; (3) evidence was adduced at the trial on behalf of accused by medical witnesses and others to rebut the testimony of the Crown doctors as to his insanity; and (4) accused himself gave evidence on his own behalf, thereby affording an opportunity to the jury to form an opinion for themselves on the question of his sanity or insanity from his behaviour. demeanour, and mode of witness-giving. In the previous case the accused was incarcerated in an asylum on account of an alleged crime which was not proved against him; in this case no attempt was made by the accused to deny the crime charged against him, but he declared himself to be some and that he would rather suffer ten years in prison than suffer incarceration in an asylum. Both cases are alike in that the whole case -alleged insanity and alleged crime-was placed before a jury, but while in the previous case present insanity was proved the alleged crime was not proved; in this case the alleged crime was proved and the alleged insanity was not proved.

The fifth case, which may be called the Wigtownshire case. contains also certain points of interest respecting lunacy procadure associated with crime. The accused, soon after the commission of the act of shooting and killing his aunt, was sent to an asylum—Perth Lunacy Prison—by the authorities under the terms of the Act of 1857, Section 89, or of the Act of 1862, Section 15. After a residence of eight years in that place he recovered his sanity, was liberated, but was at once arrested on the charge of murder. At his trial the fact that he was found to be insane at the time of committing the act and was placed under care in Perth Lunacy Prison was sufficient evidence of non-liability for the consequences of his act, and the evidence of the medical witnesses satisfied the court that he had now recovered his sanity. But although he was acquitted by the jury on the ground of his insanity at the time, he could not be there and then liberated by the court, but could only be freed after petition and by order of a Secretary of State.

The last case cited (Case 6) is in some respects the most extraordinary case of the series. Here was a man who brutally murdered his wife, who was duly tried and duly defended, whose mental condition had been examined by medical persons who could not, however, declare him to be of unsound mind, who is found guilty and is sentenced to death, on whose behalf there was no recommendation to mercy by the jury nor petition for reprieve by the public, but whose execution does not take place owing to what seems a very unusual intervention of the Secretary for Scotland. It is not publicly known at whose instance the attention of the Secretary for Scotland was called to the case, but the fact remains that by his instructions a comsission of lunacy experts was sent 15 days after the trial and six days before the date of execution to the prison in which the condemned man was confined for the purpose of examining him. These experts are presumed to have reported to the Secretary for Scotland, but what was contained in their report is not publicly known. It was publicly announced, however, several hours before the time appointed for the execution to take place that he was reprieved and his sentence respited to penal servitude for life. This procedure gave rise to considerable discussion at the time, and one of the questions then canvassed was the legal position of the Secretary for Scotland in so acting. I have not been able to discover by what powers under the Scottish Emacy Acts the Secretary for Scotland acted. There is a form of procedure in Section 89 of the Act of 1857 which provides that "in the case of a prisoner who exhibits insanity when in confinement as a prisoner under any sentence or under any charge of any crime or offence or under any civil process, the sheriff shall inquire, with the aid of two medical meens, as to the insanity of such prisoner, and if it shall

such prisoner is insane, it shall be lawful for one of His Majesty's Principal Secretaries of State, upon receipt of such certificate, to direct by warrant under his hand that such person shall be removed," &c. This procedure does not seem to have been followed in the present case, because the condemned man was not respited during His Majesty's pleasure, but respited to penal servitude for life; for if a certificate of insanity after inquiry had been sent to the Secretary for Scotland, the condemned man would have been removed from prison to an asylum, and would not be condemned to penal servitude for life.

It has been suggested in some quarters that this points te a movement toward the abolition of capital punishment. It is only human that juries should shrink from returning verdicts which involve the lives of prisoners, and, perhaps, the histories of several recent cases show a trend of opinion in this direction. I offer no opinion on the question of the propriety or otherwise of such abolition, but so long as capital punishment finds a place on the statute-book the same should be awarded where the law demands it until it be recealed.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON AN INTERESTING CASE OF MELANOTIC SARCOMA.

BY HENRY BURNS, M.B., CH.B. EDIN., SURGEON, ROTAL MAYY; HOUSE SURGEON TO THE DUMPRIES AND GALLOWAY BOYAL INFIRMABY.

The patient, a man 25 years of age, was admitted to the Dumfries and Galloway Royal Infirmary on July 13th, 1909. His family history was good and free from any story of malignant disease. The personal history showed that about eight months before admission, while at work as a mason, a large stone fell on his left inguinal rezion. He quite recovered from this accident in a few days and resumed work. Three weeks before admission he noticed a swelling in his left inguinal region and another on the back of his left heel, but he could not state which appeared first. The swellings were neither painful nor tender. That in the groin, at first quite small, gradually grew larger and "black spots" appeared in the skin over and around it; that on the heel, he said, consisted of a hard mass, painful only when his boot pressed upon it, and about the size of a halfpenny. About ten days before admission he observed small black swellings on other parts of his body, chiefly on his chest. He stated that he had been losing weight and strength for some time.

On examination numerous swellings could be seen and felt in the upper part of Scarpa's triangle and in the inguinal region of the left side. They varied in size from that of a pea to that of a walnut; they were hard and neither painful nor tender. The skin over them and for a considerable distance around was studded with small black spots, the whole having a very mottled appearance. On the back of the left heel a swelling, with a circumference equal to that of a four-shilling piece and projecting about a quarter of an inch beyond the skin surface, could be seen. It was coal-black and densely hard, and neither painful nor tender. On other parts of the body—the chest, abdomen, axillæ, and limbs—small lumps could be seen and felt scattered about in the subcutaneous tissue, the ones nearer the surface being black. These were fairly hard and neither painful nor tender. The left lower limb was greatly swellen and cedematous. The patient was quite cheery about himself and his condition. The breath-sounds cheery about himself and his condition were harsh in character. The liver was not enlarged, and the urine contained melanin. A small lump was excised from the left forearm and examined. It showed the structure of a melanotic sarcoma.

in confinement as a prisoner under any sentence or under any charge of any crime or effence or under any civil process, the sheriff shall inquire, with the aid of two medical persons, as to the insanity of such prisoner, and if it shall be certified by such sheriff and such medical persons that

The breathing was now somewhat laboured and the breath sounds were harsher in character. The left leg became more cedematous and ascites developed. By the 20th the mass on the left heel had broken down and so also had a swelling in the right gluteal region. The black nodules had greatly increased in number all over the body and one had appeared on the forehead. The breathing was more laboured and cough had started. The patient was now very depressed and could not sleep except under the influence of morphine. There was dulness over both bases of the lungs and the anterior edge of the spleen could be palpated. On the 26th the abdomen was extremely ascitic and was tapped, 200 ounces of yellowish fluid being drained off. A Southey's tube was inserted. For the next three days the amount of fluid drained off was 50, 62, and 25 ounces respectively. Breathing became very difficult and cough very troublesome. The patient became very restless. On the evening of August 30th he became very cyanosed and died in a few minutes. Throughout the whole course of his illness he never once complained of pain.

Post-morten examination.—The abdomen and pleural sacs were full of fluid. The omentum was densely infiltrated with the growth and was absolutely black all over. The stomach was affected, as were also the small intestine, large intestine, and rectum. In the liver were several small scattered black nodules; it was slightly increased in size. The spleen was enlarged and had numerous small nodules in it. On cutting it a growth of about the size of a Tangerine orange was discovered and was easily shelled out. The kidneys were not affected. The bladder had numerous nodules in its walls. The peritoneum was studded with nodules. Both lungs were infiltrated with the growth and nodules were found in the pleura and pericardium. The mediastinal tissue was also infiltrated. The sternum itself was black with the growth and could be broken fairly easily. Neither testicle was affected, but the scrotal tissues were greatly indurated. The swellings in the left inguinal region and on the left heel were black all through.

Dumfries.

A NOTE ON THE REMOVAL OF FOREIGN BODIES FROM THE STOMACH.

BY BILTON POLLARD, F.R.C.S. ENG., SURGEON TO UNIVERSITY COLLEGE HOSPITAL, LONDON.

I HAVE recently extracted a two shilling-piece from the stomach, of a girl, aged 15 years, without cutting into the stomach, in a way which I have not hitherto seen mentioned, and a short note on the method adopted may perhaps be of interest.

The method was as follows. The operator opened the abdomen by a longitudinal incision through the upper part of the left rectus muscle and seized the coin through the wall of the stomach with his finger and thumb; an assistant passed a flexible forceps, described below, by the mouth into the stomach. The coin was adjusted in the grip of the forceps and care was taken to avoid inclusion of mucous membrane; the assistant then withdrew the forceps and with it the coin.

The method of extraction outlined above was devised by me several years ago in order to remove a halfpenny from a little child's stomach, but it was not then put into practice as the coin was eventually passed per vias naturales. For that case I had had a long flexible forceps made after the pattern of Durham's tracheal forceps. The principle of the forceps is the same as that of Toynbee's well-known forceps for the ear. The blades of the instrument, which when uncontrolled spring apart, are fixed to a piece of copper wire, around which a tube composed of spirally coiled wire is placed. The instrument is operated by the handles in such a way that the wire tube slides over the blades of the forceps and brings them firmly together.

For the extraction of the two-shilling piece this instrument was passed with the blades closed. The coin was removed at the first attempt in the way already described. No resistance was felt when the coin passed through the cardiac orifice, nor indeed at any part of its transit through the cesophagus. The abdominal incision was sutured in layers and the patient made a normal recovery.

Harley-street, W.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

LARYNGOLOGICAL SECTION.

Exhibition of Cases and Specimens.

A MEETING of this section was held on Nov. 5th, Dr. J. DUNDAS GRANT, the President, being in the chair.

The following cases and specimens were shown:-

Mr. G. SECCOMBE HETT: Post-mortem specimens from a case of Chronic Glanders in a man aged 24 years. The principal visible lesions during life had been ulcerations within the mouth, nose, and pharynx. In the lungs and liver the strong resemblance to tertiary syphilitic lesions was noted.

Dr. Dan McKenzie: Perforation of the Nasal Septum from Salt Dust in a woman employed in a salt factory. Three other females, out of a total of eight employees, were affected to a less extent. Microscopical sections from the marginal tissues showed typical giant cell systems.

Dr. STCLAIR THOMSON: 1. A woman, aged 46 years, affected with Tuberculosis of the whole of the Left Vocal Cord and the Interarytenoid Space, in whom consolidation of the right apex had been diagnosed. The lesions were completely healed by two months' silence and sanatorium treatment. 2. Two patients, in whom Tuberculosis of the Epiglottis, Cords, Interspaces, and Folds of the Larynx respectively had been arrested by galvano-cautery and sanatorium treatment. It was pointed out that tuberculosis developing in the larynx after the process had been arrested in the lungs did not generally assume an acute form, but was apt to become extremely tedious; also that, in spite of a fair amount of active mischief in the chest, the temperature began to improve with the improvement in the larynx. 3. Papilloma of the Larynx in a boy, aged 6½ years, of four years' duration, cured by trachentomy and repeated operations with direct laryngoscopy. This case showed the persistent recurrence of papillomata in spite of frequent and complete removal and the natural tendency of the disease to disappear about the age of 6 years. It also emphasised the advantage and harmlessness of wearing a tracheotomy tube, and occasion was taken to decry the useless and crippling employment of laryngo-tracheotomy, as recently proposed, in these cases. 4. A woman, aged 56 years, a ter Laryngofissure for Subglottic Enchondroma. After having previously shown before the section in 1908 by Dr. A. Stanley Green and Dr. H. Lambert Lack, the enchondroma had been finally removed by laryngo-fissure by Sir W. Watson Cheyne.

Dr. W. Jobson Horne: A case of Laryngeal Neoplasm presenting Unusual Features in a woman, aged 65 years. The growth occupied the posterior half of the right side of the larynx and appeared to spring from the ventricle or ventricular hand. Pieces had been removed at intervals for microscopical examination, and these sections were referred to the morbid growths committee for report.

Mr. W. STUART-LOW: Three cases of Inoperable Carcinoma, extra-laryngeal, pharyngeal, and lingual respectively, in whom ligation of the thyroid vessels for partial ablation of the enlarged thyroid gland had been performed with great benefit.

The PRESIDENT: 1. Infiltration of the Left Ventricular Band. The patient was a woman, aged 62 years. The infiltrated band bulged so as to cover the whole of the left cord and the anterior part of the right one, occasionally dipping between the cords and preventing approximation. Microscopical examination revealed only inflammatory hyperplasis, and the diagnosis lay between neoplasm and tuberculosis. 2. Epithelioma of the Right Vocal Cord in a man, aged 60 years; removal by thyrotomy. Microscopical examination of the conical outgrowth below the right cord showed early epithelioma. At the operation the right vocal cord with portion of the right arytenoid cartilage were removed and the underlying cartilage was freely scraped. The patient returned home nine days after the operation greatly benefited.

The PRESIDENT and Dr. McKenzie showed a case of Epishelioma of the Left Vocal Cord Removed by Thyrotomy.

Mr. H. CLAYTON FOX: Paralysis of the Right Vocal Cord

in a case of Myotonia Atrophica in a man, aged 57 years, who was exhibited in May, 1908, when the opinion of a neurologist was recommended. Dr. Frederick E. Batten supplied an analysis of the case, which was now shown to elicit opinions as to whether the laryngeal lesion was part of the general condition or otherwise.

Dr. IRWIN MOORE showed a case of Partial Fixation of the Left Vocal Cord of 21 years' duration in a man aged 57

vears.

Mr. NORMAN PATTERSON: A case of Swelling on the Left Side of the Neck accompanied by Dyspnœa in a male, aged 28 years, for diagnosis. The swelling was opened and the dyspnœa relieved. A sinus remained, along which a probe could be passed for a considerable distance. There was a globular swelling in the region of the left arytenoid and there were signs of tuberculosis of the right apex.

Dr. H. J. DAVIS: A case of Acute Pemphigus of the Larynx in a woman, aged 40 years. Seven days previously dysphagia and loss of voice intervened. There were bulke all over the body, and the mucous membrane of the nose, lips, tongue, and pharynx were also affected. The condition of the fauces somewhat resembled secondary syphilis. The larynx was raw and blistered, and the cords were a brilliant crimson.

Dr. D. R. PATERSON: Soft Foreign Body in the Bronchus of a child, aged 6 years. A portion of "ground nut" (Arachis hypogea) had been impacted in the right bronchus for six weeks. It was removed entire, under chloroform through a 7 mm. tube by means of a telescopic forceps having the fenestrated "bean" point. The child made a good recovery.

Dr. G. WILLIAM HILL: (1) A man recently operated on for Epithelioma of the Vocal Cord and ventricular band by laryngo-fissure (a new operating laryngoscope was used); (2) two cases of Malignant Tumours of the Neck to show improvement under treatment by radium; and (3) Epithelioma of the Nasal Vestibules; surgical removal followed by recurrence; now being treated under radium.

BALNEOLOGICAL AND CLIMATOLOGICAL SECTION. Presidential Address.

A GENERAL meeting of this section was held on Oct. 29th, Dr. ERNEST SOLLY, the President, being in the chair.

The PRESIDENT announced that in pursuance of a resolution passed at the last general meeting the British Balneological and Climatological Society had become converted into a section of the Royal Society of Medicine, dating from Oct. 1st. Dr. Solly then vacated the chair, which was taken by the new President, Dr. LEONARD WILLIAMS. A vote of thanks was proposed to the President, the officers of council, and the secretaries by Dr. Theodore Williams, and seconded by Mr. W. LOVE, and responded to by Dr. Solly, Dr. F. BAGSHAWE, Dr. R. FORTESCUE FOX, and Dr. F. A. DE T. MOUILLOT.

An ordinary meeting was then held, Dr. LEONARD WILLIAMS, the President, being in the chair.

A paper by Mr. J. J. EYRE (Naples), entitled "The Hygiology of Naples," was brought forward and taken as read.

The PRESIDENT then delivered his address entitled "To Redress the Balance," which was published in THE LANCET of Oct. 30th.

Dr. HARRY CAMPBELL proposed, and Dr. G. W. HAMILTON CUMMING seconded, a vote of thanks for the address, and the President replied.

At 7.30 the same evening the annual dinner was held at Oddenino's Restaurant, Dr. W. Hale White, Dr. H. D. Rolleston, Dr. W. P. Herringham, and Dr. Septimus Sunderland being the guests of the section.

During the evening a presentation was made to Dr. Sunderland in recognition of his services to the society.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION.

Antisoptic Inhalations in Early Pulmonary Tuberculosis.—
The Pharmacological Action of Apocynum Cannabinum.

A MEETING of this section was held on Nov. 2nd, Professor A. R. Cushny, the President, being in the chair.

Dr. DAVID B. LEES read a paper in which he strongly advocated the use of antiseptic inhalations in early pulmonary tuberculosis. Wearing continuously an oro-nasal respirator never developed into professional advocates. The system.

of a simple pattern, the patient inhaled the vapour from a solution of carbolic acid, creasote, spirit of ether, and spirit of chloroform. He considered that by this means the disease had been effectually cut short in a series of 30 cases, particulars of which he gave.—The paper was discussed by Dr. W. EWART, who emphasised the fallibility of physical signs. There were present, even in health, great differences in the character of the percussion note and the breath sounds.—Dr. J. GRAY DUNCANSON agreed with Dr. Lees that inhalations were of great value in lessening cough and expectoration.—The PRESIDENT doubted if the effect could be correctly described as antiseptic. The vapour could only be inhaled in very small concentration.

Dr. H. H. Dale read a paper upon the Pharmacological Action of Apocynum Cannabinum. He traced the history of the drug and the vicissitudes which its reputation had undergone. By some it had been dismissed as worthless, by others it had been described as an unfailing specific for dropsy, ascites, and even hydrocephalus. Working independently two recent investigators had each isolated a crystalline substance from the commercial apocynum which was shown by Mr. P. P. Laidlaw and himself to possess a marked digitalishe action. This substance, unlike the crude preparation, possessed no emetic and no cathartic action. Independently of its action upon the heart and blood pressure no specific diuretic effect could be demonstrated. Dr. Dale illustrated his paper by throwing upon the screen records of the heart beat, blood pressure, and urinary outflow which showed the characteristic action of the drug.

MEDICO-LEGAL SOCIETY.

Presidential Address by Sir John Tweedy.

THE first meeting of the session of this society was held on Oct. 26th.

Sir JOHN TWEEDY, the President, delivered an opening address on the Historic Status of the Professions of Law and Medicine. In studying the history of surgery, he said, he had often been impressed by the frequency with which law and medicine had been found in juxtaposition, sometimes, it was true, at variance, but more often in association as joint labourers in the advancement of knowledge and in the struggle for freedom of thought. It was indeed remarkable how the status and vicissitudes of these two professions had been affected and influenced by the social, economic, religious, and political life in different countries and in different ages. In the Middle Ages law and medicine were the only two secular studies, and they stood in somewhat similar relations both with respect to society and to ecclesiastical authority. During the period of the invasions of the barbarians in western Europe from the fifth to the ninth centuries the scanty remnants of learning were almost entirely in the hands of ecclesiastics, and the practice of medicine was almost monopolised by the regular clergy. Many monks after taking the vow and assuming the habit left their monasteries to follow the secular callings of law and medicine, and so common did the practice become that in the twelfth and thirteenth centuries various councils of the Church or bulls of the Popes forbade the monks to study either civil law or medicine. It was further decreed that anyone leaving a monastery for this purpose without special permission and not returning within two months should be excommunicated. The effect of this upon the practice of medicine was to create a division between surgery and medicine. Many ecclesiastics continued to practise as physicians, but being forbidden to engage in surgical operations, either propter indecentiam, or in accordance with the maxim ecclesia a sanguine abhorret, abandoned surgery to laymen and came to despise it as a mere handicraft. Such was the origin of modern surgery.

If we cast our glance backwards to ancient Greece and ancient Rome we find a remarkable dissimilarity between the relative status of the two professions. In ancient Athens, while medicine was highly organised, professional lawyers had scarcely come into existence. Hired advocates were expressly forbidden in courts of law, every citizen being presumed by law to be capable of pleading his own cause. A nervous or inexperienced speaker could obtain permission from the judges to call a "friend" or relation to support him, but these friends

however, created a class of men who made a business of composing speeches to be learned and delivered by others, but the name " $\lambda o \gamma o \gamma \rho d \phi o s$ " was a reproach, and the perfection of the composer's art was to mask his identity and to disguise his legal learning. This, be it remembered, was at a time when Hippocrates, the Father of Medicine, was collecting or compiling that great body of medical doctrine and practice which dominated Europe for 20 centuries and became the true source of modern medicine.

In ancient Rome, on the other hand, there were but two professions-arms and law. By the one it has been said the Romans conquered the world; by the other they governed it. Medicine as a profession can hardly be said to have existed at all at this time, and the treatment of disease was chiefly by traditional family recipes founded partly on experience and partly on superstition. Most of the physicians who practised in ancient Rome were Greeks, some doubtless mere adventurers, who flocked to the city in search of fame or wealth. There were no legal ordinances regulating the character of medical training, and students acquired their knowledge how and where they liked. The remarkable difference between the position and status of lawyers and medical men in ancient Greece and in ancient Rome was apparently determined by the ethnological, social, and political differences of these two great peoples. All the Greeks claimed a close relationship and a common origin. The Greek citizen was a pronounced individualist and possessed "the love of freedom without the spirit of union." The Romans, on the other hand, were a people made up of many races, and in Rome individualism was suppressed and its activity transformed into a collectivism which concentrated all its energies and activities upon the affairs of the State.

Turning again to the Middle Ages, we find the character and subjects of study largely determined by social, religious, and political conditions. The cloister was the retreat for the learned, and the only subject that was thought worthy of serious study was theology as a preparation for the calling of priest or monk. In the great University of Paris in the twelfth and thirteenth centuries there was no systematic teaching either of medicine or of civil law. Indeed, the study of civil law was for a long time prohibited, as likely to interfere with the study of theology and with ecclesiastical authority. In the south of Europe medicine and law were actively cultivated; indeed, medicine had been studied with considerable success in the school of Salerno as far back as the ninth century. But towards the end of the eleventh century there began the revival of the study of medi-cine and of civil and canon law in the universities of northern Italy, especially Bologna, partially brought about by the introduction of Arabian writings from Spain. In Italy, secular education had never been completely extinguished, as it had been in the north. The educational traditions of the old Roman world were never entirely When the revival of learning came its most striking effects were seen not in the church schools, but in the schools of independent lay teachers. Between Paris and northern Italy there was, furthermore, a difference in the classes from which students were drawn. It was customary, as Rashdall, in his admirable "History of the Universities of Europe in the Middle Ages," remarks for the Lombard nobility to give their sons a literary education at a time when the knights and barons of France and Germany were inclined to look upon reading and writing as unmanly accomplishments fit only for priests and monks, and especially for monks not too well born. In these circumstances. in Paris, learning manifested itself chiefly in dialectics, especially as applied to metaphysics and theology. In Italy, on the contrary, grammar and rhetoric were the two important studies chiefly as preparation for the work of the notary and pleader. In England the New Learning of the sixteenth century was largely helped by an eminent lawyer and an eminent physician. Sir Robert Rede, Chief Justice of the Common Pleas, founded in 1518 in the University of Cambridge three lectureships on history, logic, and philosophy, which in the year 1858 were consolidated into one which still bears his honoured name. About the same time Thomas Linacre went to Italy for the purpose of learning Greek, and on his return to Oxford taught medicine and Greek. Linacre revived classical medicine in England, wrote grammatical and medical works, and translated from the Greek writers, especially from Galen. To him chiefly is

owing the foundation of the Royal College of Physicians of London by Royal charter in the year 1518.

One might collect many other instances from the pages of the history of civilisation of the parts which lawyers and medical men have played in the spread of learning, in the defence of liberty, and of freedom of thought. The formation of this society may be regarded as the crown of this common endeavour. In the growing complexity of civilised society fresh problems are continually forcing themselves upon the attention of thoughtful men. Considerations of public health and well-being have fostered the growth of legislation relating thereto. Much of this legislation, though well-meaning, is imperfect, and very often unscientific and futile, largely, I believe, because legislation has not kept pace with the advance of medical knowledge. A new Organon is required in the investigation of medico-legal cases. The legal maxim, De jure judices de facto juratures respondent is, I believe, sacrosanct in the legal mind. To the judge, rightly, is given the interpretation of the law, but to leave to an untrained and unscientific jury the decision as to facts respecting a disputed medical case is very often, I submit, a travesty of justice. Has not the time come for a radical reconsideration of the whole question of medical evidence in courts of law? Perhaps the increased employment of medical assessors in cases where medical or surgical facts or opinions are in dispute would do much to prevent the unpleasant exhibitions which are now too often witnessed in the law courts when cases of this kind are under investigation. This society may perhaps do much to bring about the required readjustment, and if so by this attempt alone its foundation will have been amply justified.

LIVERPOOL MEDICAL INSTITUTION.

The Surgical Treatment of Chronic Constipation.—The Therapeutics of Pituitary Extract.

A MEETING of this society was held on Nov. 4th, Mr. T. H. BICKERTON, the President, being in the chair.

Mr. R. W. MURRAY read a note on the Surgical Treatment of Chronic Constipation. This condition when calling for surgical interference was met with chiefly in women who had suffered from mucous colitis. Reference was made to cases of this nature related by Mr. W. Arbuthnot Lane, who recommended and practised removal of the large bowel. Mr. Murray did not consider so serious a measure justifiable or necessary. Some years ago he suggested treating chronic constipation by bringing the appendix to the surface in order that through it the large bowel might be thoroughly irrigated. Several cases were related in which this had been done with very satisfactory results. -Mr. F. T. PAUL said that he had dilated the anus in cases of uncomplicated chronic constipation with very good result. He thought that Mr. Murray's cases were at least complicated by, if not altogether due to, colitis. He had several times used appendicostomy for this condition and always with success. He wanted to know its value for simple intense constipation. -Dr. J. LLOYD ROBERTS referred to a case of mucous colities in which after appendicostomy the pain caused by the lavage was so severe that the treatment could not be proceeded

Dr. W. Blair Bell read a paper on the Pituitary Body and the Therapeutic Uses of the Infundibular Extract in Shock, Uterine Atony, and Intestinal Paresis. After dealing with the work of other investigators who had confined their attention mainly to the anatomy and development of the pituitary body and to the physiological action of the infundibular extract upon the blood-vessels and kidneys, Dr. Blair Bell described the results of his own experiments carried out with Dr. Pantland Hick, and already published, not only upon the blood pressure but also upon the uterus and intestines. Further, he gave an account with cases of the clinical use to which he had put the extract. Hitherto it had only been used as a diuretic in tabloid form. With a hypodermic preparation which had been made for him by Messrs. Burroughs, Welloome, and Co., both for his experimental and clinical use, and now on the market, he had obtained most striking results. 1. In shock the prolonged period during which the blood pressure was raised made it a most valuable therapeutic agent. 2. En uterine atony powerful and prolonged contractions were

induced so that in such conditions as post-partum hæmorrhage it was specially indicated. 3. In intestinal paresis, post-operative or otherwise, immediate effects were always obtained. Dr. Blair Bell next discussed the origin of the active principle and its probable chemical com-position. He also described the method of administra-tion of the extract. Finally, he expressed his indebtedness to his surgical colleagues and other members of the medical profession in Liverpool who had so readily tested the extract and informed him of the results.— Sir James Barr congratulated Dr. Blair Bell on the value of his work. He thought that pituitary extract should be used with caution, and its misuse would bring it into disrepute. This drug was active in producing arterio-solerosis, it contracted the coronary arteries, and led to their degeneration. When used as recommended by Dr. Blair Bell with low blood pressure no mischief could result, and if reserved for such cases it would hold a valuable position in thera-peutics.—Dr. Pantland Hick, who had carried out the experimental work with Dr. Blair Bell, drew attention to the danger of using the drug in cases of heart failure.

Mr. PAUL had used it in a case of intestinal paresis after operation with the most remarkable result after all else had failed to give relief. - Mr. FRANK JEANS also had used the drug in several cases and fully confirmed its action on the intestines -Mr. A. HOPE SIMPSON and Dr. R. J. M. BUCHANAN referred to a case of splenic anzemia with distension and ascites in which the extract had given marked relief over a period of several weeks when given at intervals; the relief was maintained, there was a great diminution in the size of the spleen, and the fluid was kept in abeyance. Dr. Buchanan also referred to the opinion held by Müller and others that the centres for the involuntary action of the uterus, bladder, and rectum were situated in the pelvic sympathetic ganglia, and desired to know if the pars nervosa of the pituitary body could be regarded as an integral part of the sympathetic nervous system, or did the extract act by stimulating the ganglia? He considered that those cases of so-called acute intestinal paresis associated with peritonitis, for which operation had to be performed, were not due to any special affection of the gut itself but to paralysis of the sympathetic nervous system, and the distension was a symptom of this condition, namely, shock.—Dr. E. E. GLYNN believed that the extract would be far less efficacious in intestinal atony due to acute general peritonitis than to other causes.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Valediotory Address.—Fracture-Dislocation of Cerrical Vertebra.—Scoppolamino-Morphine Anasthesia.

THE first meeting of the eighty-ninth session of this society was held on Nov. 3rd.

Dr. JAMES RETCHIE, the retiring President, referred to the flourishing condition of the society; he then spoke of the debt of gratitude which it owed to Dr. William Craig, who for 28 years had been editor of its Transactions, also to Mr. David Wallace, senior secretary, both of whom had resigned their offices. He also referred to the many serious losses which the society had suffered from death. Dr. Ritchie then addressed the society on "The Influence of the Tissues of the Body on the Incidence and the Treatment of Disease. He first referred to the rapid advance of the science of medicine and the tendency of the pendulum of scientific theory to swing too widely to one side or the other. Know-ledge of the influence of micro-organisms on health and disease showed their great importance, but he believed that there was the tendency to overlook the influence of the soil in which they grew, an error which laboratory workers did not make. In relation to diseases other than micro-organismal, the importance of the constitution did not receive sufficient recognition. He spoke of the chemico-vital processes of the tissues of the body, of the different qualities of plasm and the influence of heredity on these qualities, and gave illustrations from medical practice of the influence of these on health, disease, and longevity. He adverted to the differences and varieties of constitution and described as types, gouty, chemmatic, nervous, bilious, and tubercular, not in relation to external characteristics, but to chemico-vital peculiarities of the cells of various tissues. He next considered the relation of some pathological organisms to the tissues in health, lowered vitality, disease, and injury, referring to immunity, acquired and transmitted, as evidences of the influence of the tissues, specially the blood. He then treated shortly of the necessity of maintaining the power of resistance of the tissues as a prophylactic measure, in addition to the important work of waging a crusade of extermination if possible of pathological organisms. As to treatment of disease, he emphasised the fact that we did not treat diseases as entities, but we treated individuals who suffer from diseases which were modified by the constitution, and that treatment should be modified accordingly. Dr. Ritchie concluded by welcoming Dr. Byrom Bramwell to the presidential chair.

Mr. DAVID WALLACE and Dr. A. BRUCE showed a case and read a communication on a case of Fracture-dislocation of the Axis Vertebra occurring from a unique cause. The patient, a healthy man, aged 40 years, a marine engineer, hearing someone speak behind him, turned his head suddenly and felt a slight crick in his neck. Shortly afterwards he felt a lump in the back of his neck and found that he could not move his head to either side and only slightly forwards and backwards. The occurrence of pain in the back of the head, neck, and shoulders some time later led to a diagnosis of rheumatism. The patient's physician, Dr. W. W. Millard, finding on his return to this country a projection of the back of the neck, consulted Mr. Wallace who diagnosed a dislocation of the upper part of the spine, which was confirmed by a skiagram. There being no loss of motor power in either the upper or the lower limbs it was thought well not to attempt reduction. Some weeks afterwards a slight accident (a child pulling on a shawl round the patient's neck) caused further displacement and produced great pain, paralysis of all four limbs and of the diaphragm, with retention of urine. Next day the patient was admitted to Dr. Bruce's ward, and on the following day, after consultation with the patient's physician, Dr. Millard, the dislocation was reduced by Mr. Wallace. There was almost immediate relief of breathing, the diaphragm commencing to act. In about ten minutes there was a return of movement of the legs, in about 12 hours voluntary action of the bladder, and in a day or two commencing return of the power of the hands. The head was retained in a fixed position backwards on the spine by means first of sand-bags and then of a poroplastic jacket with a head-piece to prevent lateral movement. The patient has made a steady recovery, interrupted only by a short pneumonic attack a few days after the reduction and a slight attack of cystitis. The bones are shown by a skiagram to be in good position. Dr. Bruce thought that the fracture had taken place at the weak point in the odontoid process which corresponded with the epiphyseal cartilage. - Dr. C. W. MACGILLIVRAY asked what was it which really happened when the first accident occurred, for he could hardly imagine that fracture with impaction of the odontoid process could take place merely by turning the head round suddenly. _Dr. BYROM BRAMWELL thought that there might have been latent disease of the cervical vertebrae without symptoms previous to the accident, and he had published a case of caries of the cervical spine in a boy, aged nine years, in which complete recovery took place after there had been total paralysis. -Mr. J. M. COTTERILL related a case which had lately been under his care of a man with fracture of the third cervical vertebra with no paralysis, and due to the patient's neck having been tightly gripped while wrestling.— Mr. C. W. CATHCART, Mr. WALLACE, and Dr. ALEX. GOODALL also took part in the discussion.

Dr. H. TORRANCE THOMSON and Dr. DENIS COTTERILL contributed a paper on the Use of a Combination of Scopolamine and Morphine as an Anæsthetic Adjunct, which we shall report in another issue. — Professor F. M. CAIRD, Mr. ALEXANDER MILES, and Mr. COTTERILL discussed the paper. The office-bearers for the session 1909-10 are as follows:—President: Dr. Byrom Bramwell. Vice-Presidents: Dr. C. W. MacGillivray, Dr. W. Allan Jamieson, and Mr. J. M. Cotterill. Councillors: Dr. Robert Thin, Dr. G. M. Robertson, Dr. James Ritchie, Dr. J. S. Fowler, Dr. John Cumming, Dr. Theodore Shennan, Mr. A. Scot Skirving, and Mr. David Wallace. Treasurer: Mr. J. W. Dowden. Secretaries: Dr. F. D. Boyd and Mr. Alexander Miles. Editor of Transactions: Dr. D. Chalmers Watson. A hearty vote of thanks

was awarded to Dr. William Craig, who had so ably edited the Transactions of the society for the long period of 28

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on Nov. 5th, Mr. C. Gordon Watson, the President, being in the chair. - Mr. Peter L. Daniel read a paper on Latency in Disease or Overlooked Infections. He said that many children born of tuberculous mothers have tuberculous disease, and that of all the children who die in children's hospitals, about 60 per cent. die from intestinal lesions, mostly incipient tubercle. About 50 per cent. of those dying from measles and scarlet fever have macroscopic disease of the antrum of Highmore, mostly a streptococcic infection which is easily lit up. Many girls have vulvar diseases, really gonorrhoal, which, if lit up, can develop pelvic lesions. Abscess of the kidney has been known to develop 15 years after an attack of gonorrheea. Pneumococci involve many areas and are largely found in peritonitis, the disease probably having spread from the thorax through the diaphragm. Many severe throat attacks are pneumococcic, the germ being latent in the accessory sinuses. Gall-stones owe their origin to the action of germs which set up catarrh of the small bile ducts. Cirrhosis of the liver is not due to the action of alcohol, but to a toxic infection. 80 per cent. of joint troubles are due to septic infection from the mouth and intestine. Sciatica is due to disease of the hip, sacroiliac or lumbar joints as a result of septic infection. instances were quoted in support of the thesis.-Dr. H. M. Spoor read notes of a case of Severe Pruritus Vulvæ in a woman, aged 37 years, which had lasted three years. On examination both nymphse were very hypertrophied and pendulous, and the surrounding parts showed that leathery appearance associated with repeated scabbing and rehealing. There were piles, which had existed for 20 years, a moist sodden condition of the epidermis, and a thin leucorrhæic discharge from the vagina. The itching was excessive, and treatment, local and general, being unavailing, an operation was decided on, in spite of the fact that the patient was then seven months pregnant. pendulous nymphæ were completely removed and the cut edges of skin united. The anterior ends of the first incisions were then joined by two curved incisions, one of which passed anterior and the other posterior to the clitoris, which, together with a small area of skin, was thus enclosed between them. This enclosed skin, together with the clitoris, was dissected away, and the wound was closed. A fresh incision was then made on each side from above and to the outer side of the mons veneris downwards, the lower part being parallel to the outer border of the vulva. The skin of the mons veneris was undercut in an outward direction between the anterior ends of these two incisions. At the posterior part of the incisions the skin was raised in an inward direction towards the vulva, and a slight undercutting was done at the outer side of these incisions. The wounds were then stitched up. The patient made an excellent recovery and was immensely relieved. No itching was felt for over a week, but slight symptoms appeared in the skin which had escaped the undercutting process, and these persist, but the inconvenience is no way comparable to the tortures suffered before.

EPIDEMIC INFANTILE PARALYSIS.—It will be remembered that our Berlin correspondent recently reported a widespread epidemic of acute anterior poliomyelitis amongst the children of Westphalia. The same thing has been happening in Holland on a smaller scale. The Leyden newspapers on Oct. 17th published the intelligence that no less than 25 children had been attacked by acute infantile paralysis and a number of parents consequently were keeping their children from school or sending them away into the country. Later intelligence showed that only 17 cases had then been officially reported, none of them of a very severe character. All the patients were under 2 years of age. The Leidsch Daghlad of Oct. 21st announced that 21 cases had up to that time been officially certified, all except 2 being in children under 5 years of age. The remaining 2 patients were aged 12 and 8 years respectively. Altogether, since the occurrence of the first cases in August, 24 have been certified in Leyder, which is a town of 55,000 inhabitants; others have occurred in a sporadic fashion in localities more or less distant from Leyden.

Rebiews and Aotices of Books.

Anatomy, Descriptive and Applied. By HENRY GRAY, F.R.S., formerly Lecturer on Anatomy at St. George's Hospital Medical School. Seventeenth edition. Edited by ROBERT HOWDEN, M.A. Durh., M.B., C.M. Edin., Professor of Anatomy in the University of Durham. Notes on Applied Anatomy, revised by A. J. JEX-BLAKE, M.A., M.B. Oxon., M.R.C.P. Lond., Assistant Physician to St. George's Hospital; and W. FEDDE FEDDEN, M.S. Lond., F.R.C.S. Eng., Assistant Surgeon and Lecturer on Surgical Anatomy, St. George's Hospital. With 1032 illustrations. London: Longmans, Green, and Co. 1909. Pp. 1296. Price 32s. net.

THE latest edition of "Gray's Anatomy" may be described as its jubilee number, and in reviewing it we may aptly repeat the opinion we passed on it 51 years ago, when the first edition appeared.1 "The student of anatomy and surgery of the present day enjoys a great advantage over his predecessors, in having at his command works on the subject of his studies, which not only facilitate his labours, but enable him to pursue his investigations in a scientific and practical manner. We are bound to say that no treatise that has issued from the press for a great number of years is more calculated than the present one to furnish the student and practitioner with an accurate view of the anatomy of the human body, and more especially the application of this science to practical surgery. We are not acquainted with any work in any language which can take equal rank with the one before us."

Although a succession of able editors (and Professor Howden has done his work as well as any of his predecessors—which is a high meed of praise) has greatly altered the original work of Henry Gray, we would extend to the present edition the same favourable judgment we passed on the first. We would note merely that "the advantages which the student of anatomy and surgery of the present day enjoys over his predecessors" have their qualifications. Instead of having to read and digest the contents of 750 pages for examination, as his predecessors did in 1859, he has in 1909 to master 1296 pages, and the number of facts described on each page has increased. The modern editions have become more and more of the nature of encyclopædias, new discoveries being packed into them as was found most convenient, whereas the first edition was a continuous narrative written by one man (polished, if tradition is reliable, by the scholarly pen of Timothy Holmes) and therefore more easily read and remembered by the student. Chapters on histology and embryology, amounting to 177 pages in the present edition, have added to the burden of the modern student of anatomy. His task has been doubled, and owing to the introduction of new subjects of study and to the great expansion of the old, the time in his curriculum allotted to anatomy has been halved. The advantages of the modern student are becoming so burdensomenay, well nigh intolerable—that some method of lightening them must be found. "Gray" is, and always has been, the favourite text-book of English students for examinations, and the editor could in a new edition make the student's task more tolerable by shortening the tedious and minute descriptions of the less essential structures, and at the same time he would improve the real practical features of the book.

On the other hand, the work of the present-day student is lightened by the lavish manner in which the last edition of "Gray's Anatomy" is illustrated. It contains 1032 figures, many of them improved by being coloured; the first edition contained 363 figures, an excessive number for an anatomical work of 50 years ago. The modern illustrations, excellent

in many ways, are a miscellaneous assortment, culled from many sources, done, some of them very indifferently, by many artists and reproduced by different technical methods. The original illustrations, most of which are retained, remind us that in the matter of anatomical illustrations we have receded, not progressed; they were a consecutive series of carefully drawn and executed wood-blocks, mostly the work of one man-Dr. Vandyke Carter. genius as an anatomical draughtsman, as most medical men are aware, did much to secure a popular success for Gray's work, but few know that he owed his training to the Council of the Royal College of Surgeons of England, which at the suggestion of Professor Owen (as he then was) gave its "students in human and comparative anatomy," whom Carter was one, a very complete training in draughtsmanship under one of the ablest artists of 60 years ago. Students at the present day still benefit by the money so wisely expended by the Council of the College.

One of the outstanding features of the first edition of this work was the introduction of Mascagni's investigations and illustrations of the lymphatic system of the human body, which were imperfectly known in England at that time. We are glad to note that in the present edition the numerous recent researches on this system have been fully noted and illustrated. Another original feature of "Gray's Anatomy" was the application of the rather dry details of anatomy to the work of the surgeon. In the present edition the physician has also been considered; the title has been altered from "Anatomy, Descriptive and Surgical" to "Anatomy, Descriptive and Applied." The sections dealing with applied anatomy have been entrusted to Dr. A. J. Jex-Blake and to Mr. W. Fedde Fedden, who have done their work most satisfactorily. The sections dealing with "regional" and "applied" anatomy have been more closely incorporated in the general text than in former editions, an alteration that has many advantages. So "Gray" remains an admirable modern text-book.

A Text-book of Diseases of the Ear. By P. MACLEOD YEARSLEY, F.R.C.S. Eng., Senior Surgeon, Royal Ear Hospital, &c. With 127 illustrations. London: Kegan Paul, Trench, Trübner, and Co., Limited. Pp. 452. Price 21s.

THE first chapter of Mr. Macleod Yearsley's text-book consists of a brief description of the anatomy and histology of the ear, together with a résumé of its physiology. The next chapter is devoted to clinical examination, and the principal points which require special comment are duly brought forward, with hints as to the causation of symptoms. These are more fully elaborated when they appear again under special diseases. Mr. Yearsley goes very fully into the tuningfork tests, and these are dealt with in a way which shows the great advances which have been made in the last few years, and Mr. Yearsley differs from many writers in freely quoting English authors in support of various elaborations of tests, notably that of Rinné; but we notice that he considers paracusis Willisii is not such an unfavourable symptom as is generally supposed. The third chapter deals with diseases of the external ear and the fourth with injuries and diseases of the membrana tympani, to which condition rather more time and space are devoted than is perhaps commensurate to its importance. Then follows a description of the injuries and diseases of the middle ear, in which, amongst a mass of useful matter, a dissertation appears on the correct method of nose-blowing to be used as a prophylactic measure against middle-ear infections. Suppurative conditions of the middle ear form the subject-matter of the sixth chapter, with diseases of the mastoid in the seventh, and intracranial

complications in the eighth, these three chapters dealing very fully with the whole range of suppurative otitis media. The description of the Schwartze operation would be better for more detail; the beginner would find it extremely difficult to perform the operation under the instructions given, and the so-called essentials of simple opening of the mastoid are a little vague; for instance, why is it suggested that exposure of the sinus, presumably the lateral sinus, is considered essential? We do not think this is in agreement with the views of most aurists. Though the description is too meagre for the novice it is quite sufficient for the practitioner who wishes merely to refresh his memory. In the ninth chapter Mr. Yearsley treats of subacute and chronic catarrhal otitis media, and in the tenth deals with otosclerosis. The latter chapter gives a complete and very full account of what is known concerning this most obscure complaint and will prove of exceptional interest especially to those who are unacquainted with the latest works on the subject. Under Internal Ear Diseases the labyrinthine operations for vertigo and tinnitus are considered. It is a pity that Mr. Yearsley does not give a full report of the various tests for diseases of the posterior portion of the labyrinth, more especially those elaborated by Bárány. The influence of diseases of the ear described in the twelfth chapter forms interesting reading, though a fuller consideration of the part played by arterio-sclerosis is advisable. The book is well printed and very readable; the illustrations, however, are of unequal merit. We think that this work will prove a very useful addition to the aurist's library. It contains much useful information supplied in a clear, readable, and accurate manner, and shows throughout that it has been written by one with wide experience and sound judgment.

Immunity and Specific Therapy. By W. D'ESTE EMERY, M. D., B.Sc. Lond., Clinical Bacteriologist to King's College Hospital, and Pathologist to the Children's Hospital, Paddington Green; sometime Lecturer on Pathology and Bacteriology in the University of Birmingham. With illustrations. London: H. K. Lewis. 1909. Pp. 448. Price 12s. 6d. net.

Such a work as that here reviewed appeals to a large circle of readers and is of interest not only to the scientific worker but also to the practising physician and surgeon and to the intelligent layman. The subject of immunity is often regarded as though it were divorced from practical medicine, but however inadequate our knowledge may be our plan of medical treatment cannot fail to be coloured by our conception of the natural methods of recovery from disease, and should indeed be based on an intelligent appreciation of these methods. We are, therefore, indebted to Dr. Emery for this lucid account of the present position of our knowledge of immunity. The task he has undertaken is both difficult and somewhat thankless—difficult since as yet we have no thread to guide us through the maze of researches, and thankless in that such a work falls behind in detail even in the writing. In this, however, there is compensation since mere flux of time renders previous works of the same kind inadequate. In the present state of our knowledge it is impossible to find a simple and single explanation of immunity; rather there is evidence of a multiplicity of methods for securing this condition. It is essential, therefore, that in considering the various theories advanced the author should not be a partisan but should hold so far as is possible a judicial attitude in considering the evidence for and against the explanations suggested. Such an attitude is a distinguishing feature of the book. The theories of Ehrlich have played a great part in elucidating our conceptions of immunity and have proved fruitful in suggesting lines of

investigation, but there is no doubt that with the numerous complexities which are introduced to meet new facts the side-chain theory tends to become rather an expression of these facts in the terminology of the theory than an explanation of the phenomena. It is, too, becoming more and more evident that the results of many of the experiments adduced in its support are explicable in terms of the physical and chemical properties of colloidal Due weight is given to the humoral conception of immunity, but the author appears to end, almost anwillingly, by regarding the phagocyte as of prime importance not only in the combat against infectious disease but also in the struggle against intoxication. The book is not based on original work, and differs, therefore, from the recently published studies by Muir and Browning, but in the later part of the work, and especially in that concerned with specific therapy, the author draws on his experience in estimating the value of the methods used or suggested. Besides the non-partisan spirit in which the theories are discussed, to which reference has already been made, great skill is shown in the way facts only to be found in the detached papers of various investigators are marshalled into their proper places in the chain of argument.

The strange, redundant, and confusing nomenclature which has grown up around the theories of immunity adds not a little to the difficulty of understanding them. The author wisely prefixes a glossary of the terminology with definitions and explanations. Some slips in the book itself seem to show that this is not an unnecessary precaution.

After a preliminary chapter on the meaning of immunity and its relation to recovery from disease the author passes to a chapter on the nature of bacterial toxins as a preliminary to the consideration of immunity to toxins. This involves a review of the subject of antitoxins and of the relations existing between toxin and antitoxin, with the rival chemical hypotheses of Ehrlich and Arrhenius and Madsen, the physical theory of Bordet, and the view that the facts are to be explained by the colloid nature of the interacting bodies. Though naturally humoral ideas are prominent in this part of the work, yet the author accepts the French view that leucocytes play a part in toxin immunity, and draws attention to the fact that recovery from a toxic disease, such as diphtheria, is not brought about exclusively or even mainly by antitoxic action.

The more complicated phenomena of bacteriolysis are next treated with the same lucidity which marks the earlier portion of the work, and with the aid of excellent diagrams which place clearly before the reader the problems and their suggested explanations. It is probably unavoidable in the present state of our knowledge, but it is illogical to invoke a hypothesis as an explanation of one set of phenomena which has already been rejected as untenable when discussing the results of other experiments. After considering agglutinins and precipitins a long chapter is devoted to phagocytosis. In this opsonins and their action are included. The author agrees with the views of Dean and Muir that the thermolabile opsonin is an alexin and the thermostable opsonin a true antibody; he would also regard the immune body as able to function as an openin in such dilutions that no bacteriolytic effect would be produced. A valuable chapter on the colloidal theory of antibodies is followed by a judicial summing up of the question of immunity to bacteria, in which the conclusion already referred to as to the importance of the leucocyte is reached. A final section of the book deals with the practical application of the theories which have been discussed, and there the author's considerable experience in the diagnosis

and treatment of disease by bacteriological methods is of great value. A bibliography completes the work.

The book is attractive in appearance and well printed, but has apparently been somewhat hastily prepared for the press. There are a considerable number of slips; most of these are of small importance, but some interfere with the argument and pervert the meaning of the author. If Dr. Emery means to keep his work regularly up to date in subsequent editions it would be well if he were to read through this issue very carefully. The merits of the work are great and the defaults are trifling, but there they are.

Kompendium der Topischen Gehirn- und Rückenmarksdiagnostik. Kurzgefasste Anleitung zur klinischen Lokalisa-tion der Erkrankungen und Verletzungen der Nervenzentren. Von ROBERT BING, Privatdozent für Neurologie an der Universität Basel. With 70 illustrations. Berlin and Vienna: Urban und Schwarzenberg. 1909. Pp. 200. Price M.6.

In his preface the author states the object he has in view in adding to the number of pre-existing volumes en the diagnosis of nervous disease. A concise, practical, and didactic vade-mecum is what he would like this book to be, and it may be at once said that he has succeeded in his task admirably. In teaching so complicated a subject as the diagnosis of pathological processes in the nervous system the dogmatic method has obvious advantages, and calls for no particular apology from the teacher. If it is combined with scholarship we can rest assured that he will not be unduly dogmatic, and that the student will thereby gain a sound and working knowledge of nervous disease. Anatomy is the basis on which clinical information must be established if it is to prove really useful; dissociation of the anatomical and the clinical is fatal to what we may be allowed to call scientific physicianship. In the volume before us Dr. Bing has supplied a succinct yet sufficiently detailed account of the anatomy of the nervous system, and has not hesitated to enter into minutise whenever these will serve to elucidate clinical phenomena that may meet the student. He emphasises his various points with the aid of perfectly simple but agreeably accurate diagrams, and the professing neurologist will be struck by their originality and serviceableness. To only one or two must exception be taken, in particular that on p. 61, which purports to represent the segmental areas of the skin. It does not embody the latest and most trustworthy researches on the question, and by being too schematic merely causes confusion.

The book is divided into two parts: the first deals with the localisation of spinal cord lesions, the second with intracranial lesions. A chapter on the anatomy of the cord, in which an excellent description of exogenous and endogenous tracts and their cells of origin will be found, is followed by an account of the apparatus for the transmission of motor, sensory, trophic, and vaso-motor impulses, and the significance of disturbances in each of these is discussed from the point of view of localisation. By study of the data which the author sets out methodically and lucidly the student should have no difficulty in diagnosing a given lesion; its vertical level and its position on that level should alike be determined with a fair amount of ease. Relatively to the space devoted to the cord, too little, in our opinion, has been reserved for a consideration of intracranial disease, yet it is pleasant to find so much incorporated that has not elsewhere, as far as we are aware, found its way into a text-book. This is the case more especially with cerebellar diagnosis. The handling of cranial nerve localisation is exceedingly good; the description of the semeiology is unusually complete and well worth the many pages devoted to it.

By way of criticism a few remarks will suffice. is undesirable to figure thalamo-spinal tracts when the most recent investigation limits these to a few descending fibres in the posterior longitudinal fasciculus. An anatomical connexion between the seventh cranial nerve and the twelfth nucleus is now discredited. The symptoms of disease of the basal ganglia and of the hypophysis, to mention but one or two, are sketched rather inadequately, and if atypical hemiplegias are to be mentioned at all chronic progressive hemiplegia might have a place among them. It is not the case that in Jacksonian epilepsy bilaterally innervated muscles are always thrown into contraction synchronously on the two sides. Apart from this and similar minor criticism, we have nothing but praise for this thoroughly interesting, readable, and up-to-date presentation of a difficult subject, and we compliment Dr. Bing on having both avoided controversial topics and yet omitted nothing that the practitioner can be likely to want. The place of the book on the shelf of the student and the physician should be, we think, assured.

LIBRARY TABLE.

After-treatment of Operations: A Manual for Practitioners and House Surgeons. By P. Lockhart Mummery, F.R.C.S. Eng., B.A., M.B., B.C. Cantab., Senior Assistant Surgeon, St. Mark's Hospital and Queen's Hospital for Children, London. Third edition. London: Baillière, Tindall, and Cox. 1909. Pp. 251. Price 5s. net.—Success in operating depends often not so much on the skill with which the operation is performed, but rather on the care and attention devoted to the patient subsequently. In minor operations very little is required, but in those more serious surgical cases in which shock and hemorrhage are liable to follow the whole of the difference between recovery and death may depend on the care and attention for a few hours after the operation. In hospital practice the duty of seeing that the patient recovers from the operation itself devolves chiefly on the house surgeon, but in private practice the surgeon himself is generally responsible for what is done. We spoke favourably of this work on its first issue, for it was the first attempt to systematise the treatment of patients after operation, and the present volume only differs from the early issue in the more complete arrangement of the material and in the bringing up of the knowledge to the present date. We are glad to see an account of the use of proctoclysis in cases of general peritonitis, but it would have been well to make the description fuller, for it is hardly sufficiently detailed to enable a surgeon to employ the procedure who has never seen it.

New Ideals in Healing. By RAY STANNARD BAKER. London: T. Werner Laurie. Pp. 105. Price 2s. 6d.—Health, Physical and Mental. By C. W. JOHNSON. London: The Theosophical Publishing Society. 1909. Pp. 143. Price 2s. -The above two little books both deal with practically the same subject—that is to say, the influence of the mind over the body and the tendency of modern medicine to rely less on drugs than formerly, while endeavouring to put the body into the best condition for utilising the natural forces of resistance. Mr. Baker's book is divided into two portions, of which the first deals with the "Emmanuel Movement" in Boston, and the second with the "Social Service Department" at the Massachusetts General Hospital. As to the former, it would appear from the account given by Mr. Baker to be conducted upon sensible lines, and the clergy obviously take care not to encroach upon the territory which is rightly occupied by the physician. The latter movement is one which is decidedly a good one. It is an attempt by a large general hospital to unite such methods of help as in this country are carried out by the various Samaritan funds, health visitors, and such agencies as the Charity Organisation Society. - Mr. Johnson's book is, we must say, a lamentable instance of a work written by an earnest person, with every desire to be fair, upon a matter with which he obviously has but the slightest acquaintance. He says in his preface that he is indebted to medical friends. It is a pity that the medical friends did not save him from the error of describing a wellknown physician as "Dr. Williams Osler, lately Regius Professor of Medicine at Oxford." With his dictum that air, food, water, rest, and exercise are five necessities for health we agree, and that a person possessed of the mens sana in the corpus sanum is far less likely to break down in health than one who is not so dowered is also a truism, even if we remember that the word mens in this connexion includes the spiritual as well as the psychical side of human nature.

Pocket Medical Dictionary in Eight Languages: English, German, French, Italian, Japanese, Russian, Spanish, and Hungarian. Edited by Dr. J. MEYER, Berlin, in collaboration with Dr. O'C. FINIGAN, M.D. Berlin, M.R.C.P. Lond., Assistant Physician, German Hospital, Dalston, London, London: W. Lockwood and Co.; Berlin and Vienna: Urban and Schwarzenberg. 1909. Pp. xxviii.-788. Price 20s.—The great extension of medical literature requires that any one who wishes to be abreast of modern progress must be acquainted with more than his native language. and it is often necessary also in seeing foreign patients for the medical man to be able to express his meaning in a foreign tongue. For purposes such as these this dictionary should prove very useful, and as it deals with seven foreign languages in addition to English it possesses exceptional advantages. It is of interest to note the inclusion of Japanese in the list of the chief scientific languages; it is hardly necessary to say that the Japanese words have been transliterated, and this has also been done in the case of the Russian words, though here it was not so necessary. The arrangement of the work is as follows. The words in all the eight languages are placed in their alphabetical order, but the explanation of each word is given in German, to which the reader is referred, where he will find the eight words or phrases expressing the idea in the eight languages. For instance, if we wish to know the foreign equivalents of "pain" we look up "Pain" and find that we are referred to "Schmerz," and beneath that we find (e) pain; (f) douleur; (i) dolore; (j) itami, totsu; (r) bolj; (s) dolor; and (u) fajdalour; the letters in brackets indicating the language to which the following word belongs. The errors present, which we could detect, are very few, and this is remarkable when we consider the large number of words included, but the editor has had the assistance of a native of the country of each language represented, which was clearly the only way to ensure We may mention one slip—the French for "tongue depressor" is not pince à langue, which means tongue forceps, as given correctly in the next column. We can praise the book cordially as well conceived and carefully executed, while the printing and binding are good. We would suggest the desirability of the inclusion of some phrases and sentences if that could be managed without unduly increasing the size of the book.

A Manual for Students of Massage. By MARY ANNA ELLISON, Member of the Incorporated Society of Trained Masseuses. Third edition. London: Baillière, Tindall, and Cox. 1909. Pp. 189. Price 5s. net.—It is very desirable that those men and women who devote themselves to the practice of massage should possess an intelligent knowledge of the superficial structure of the body which they manipulate. But all who consider the subject may not be inclined to agree as to the exact amount of anatomical knowledge which it is necessary for practisers of massage to possess. On

the whole, it is probable that it is better for them to know a little too much rather than a little too little, but we utterly fail to see the object of imparting to them some of the anatomical knowledge contained in the book. For instance, what can be the object of figuring and describing the vomer or the ethmoid bone? And we think that it is rather a waste of space to devote a whole page to an account of the sympathetic plexuses. The illustrations contained in the anatomical portion are not always happy; they appear to be reproductions of pen-and-ink sketches of the bones and other objects, and many of them are certainly far from accurate; for instance, the drawings of the radius and ulna are weefully out of proportion. More useful, probably because written with fuller knowledge, are the chapters devoted to practical massage, and the description of the Nauheim treatment is likely to prove useful. A short account is given of Fraenkel's method of treatment of locomotor ataxy, and the description of the Weir-Mitchell treatment is also good. We can see no necessity for the chapter on ductless glands, which is entirely out of place in a work such as this. The description of the surface markings would have been more reasonably placed with the general account of anatomy. The plates representing the muscles are unnecessarily elaborate, and the same may be said of the tables giving the origin, insertion, action, and nerve supply of the indi-The book has many good points in vidual muscles. spite of the large quantity of extraneous matter that it contains, and we hope that in a future edition the author will exercise a wide discretion in curtailing the descriptions of anatomy so as to accommodate them more accurately to the needs of students of massage.

Home Life in Ireland. By ROBERT LYND. London: Mills and Boon, Limited. Pp. 317. Price & net.—We feel some diffidence about attempting a review of a book dealing with Home Life in Ireland, for the subject almost necessarily connotes a discussion of matters deeply concerned with both politics and religion, and with these two subjects it is not our province to deal except in so far as they may affect medical matters. But nevertheless we offer our warm thanks to Mr. Lynd for a sympathetic and brightly written book which touches at most points the at present unsolved problem of Ireland and Irish government. Mr. Lynd is an Irishman himself, but he writes, as the Book of Common Prayer says, quite "indifferently." He appreciates to the full both the faults of the governed and of the governors, and there are plenty on both sides. There is manifest room for improvement in the condition of the factory-workers in the textile trades, and the payment of home-workers is in no way better These facts are set forth with exceeding clearness by Mr. Lynd in his fourteenth chapter, facts supported by figures which are not his own but taken from the reports of Miss Martindale, an inspector under the Factories and Workshops Act. Mr. Lynd draws attention to the fact that the Irish are brought up on tea, white bread, potatoes, and American bacon, and argues that if more nourishing food were in use disease would not be so rife. Quite so; but in a desperately poor country cheapness has always to be the first consideration, but we must not allow ourselves to drift here into considering how and why Ireland is poor. Altogether Mr. Lynd's book is of extreme interest, and it is possible that some in high authority in Ireland might read it with advantage.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE (UNIVERSITY OF LONDON).—A special course of four lectures on the Diagnosis and Surgical Treatment of Diseases of the Nervous System will be given on Mondays, Nov. 22nd, Nov. 29th, Dec. 6th, and Dec. 13th, by Sir Victor Horsley, F.R.S. Oards of admission may be obtained from the secretary of the hospital on payment of 1 guinea.

Reports and Analytical Records

THE LANCET LABORATORY.

"TABLOID" HYPODERMIC, TYRAMINE.
(BURROUGHS, WELLCOME, AND Co., SNOW-HILL BUILDINGS,
LONDON, H.C.)

Tyramine is a good example of the excellent scientific work which is being conducted in the Wellcome Physiological Research Laboratories. Tyramine has been shown to be the chief active principle of aqueous extract of ergot and consists of the organic base para-hydroxyphenylethylamine in a state of purity. The tyramine hypodermic tabloid contains 0.005 gramme of the base. It is stated that the drug produces a marked rise of blood pressure with greatly improved vigour of the heart's action. Its administration is suggested in shock and for producing contraction of the uterus post partum.

HOOKER'S MILK COCOA.

(THEW, HOOKER, AND GILBEY, LIMITED, BUCKINGHAM, AND DONEMOTON HOUSE, 30, NORFOLK STREET, STRAND, LONDON.)

Analysis indicates this preparation to be of decided nutritive value. It contains all classes of food materials. proteins, fats, carbohydrates, and mineral salts in excellent proportions. Moreover, a considerable part of the carbohydrate and of the protein constituents is soluble in water. The flavour of the preparation, is attractive. We found that the total nitrogen amounted to 2.73 per cent., of which 1.61 per cent. was soluble in water. It was proved that not only did the aqueous solution contain the theobromine of the cocoa but part also of the milk protein. The fat amounted to 22.00 per cent. and consisted of a mixture of cocoa and milk fat, the latter predominating. The total soluble matter amounted to 47 per cent. The mineral matter was 4.50 per cent., containing 0.85 per cent. phosphoric acid. The preparation is a good combination of milk and cocoa constituents, which have been so modified as to render them directly available for nutrition. Its food value is indisputable.

(1) LUMIÈRE'S CRYOGÉNINE; (2) HERMOPHÉNYL; (3) HÉMOPLASE; AND (4) GELÉE.

(LONDON AGENCY, A. F. JACQUIER, 104, HIGH HOLBORN, LONDON.) These preparations obtained in the pharmaceutical laboratory of the Société des Brevets Lumière at Lyons, are well worth our readers' attention. 1. Cryogénine is described as possessing remarkable antipyretic properties whilst exhibiting little toxic action or any undesirable disturbances. It is a crystalline white, odourless powder, slightly soluble in water and easily soluble in spirit. Chemically it is meta-benzamine-semicarbazide. It is said to be prescribed, on account of its steady action, in pyrexia connected with typhoid fever, tuberculosis, pneumonia, and so forth. Cryogénine is prepared in the form of tablets and wafers, the dose varying from 15 up to 120 centigrammes. 2. Hermophényl is a comparatively new organo-mercury compound; it is, in fact, a combination of oxide of mercury with phenol sodium disulphonate. It possesses the advantage that it does not coagulate a great number of organic substances, a property which commonly leads to irritation of the tissues. It may therefore be employed for intramuscular or hypodermic injection. It is, of course, a powerful germicide and has obvious applications in surgery, while favourable accounts are given of its employment in syphilis, in urinary diseases, and in gynæcological practice. It is prepared in the form of tablets, pills, and dressings, while solutions are contained in ampoules. 3. According to our examination, hémoplase contains the iron constituents of the blood. It is a reddish liquid which shows a characteristic hamoglobin spectrum, especially

when alkalised with a few drops of ammonia. The liquid on heating coagulates. Hémoplase is administered by intramuscular injection, and its application in anæmia, tuberculosis, and bloodless conditions is regarded favourably. 4. Lumière's jelly is a special preparation which, according to French clinicians, gives remarkable results in checking persistent diarrhoa. It is quite a stiff jelly, sterilised in the autoclave at 120° C.

(1) CHLORETONE GAUZE; (2) FORMIDINE GAUZE; (3) TUBER-CULIN OINTMENT; AND (4) PHENOLPHTHALEIN TABLETS. (PARKE, DAVIS, AND Co., BEAK-STREET, REGENT-STREET, LONDON, W.)

1. Chloretone possesses not only antiseptic properties but analgesic properties also, and therefore its application to wounds as a dusting powder on gauze is of service. It is regarded favourably also in gynæcological and dermatological practice. 2. Formidine is a powerful antiseptic, being a condensation product of iodine, formic aldehyde, and salicylic acid. On its gradually dissolving, the germicidal activity of these constituents is developed. Formidine is said to be free from irritating or toxic effects, and the gauze forms a very satisfactory substitute for the old iodoform fabric. 3. The tuberculin ointment contains Koch's old tuberculin incorporated with wool fat in proportions laid down by Dr. Ernst Moro, who recommends its use for the cutaneous diagnosis of tuberculosis, considering the reaction to be fully as reliable as the von Pirquet method and less risky than the diagnosis obtained by subcutaneous injections or by the conjunctival method of Calmette. This Moro test is supplied in collapsible tubes. 4. The palatable phenolphthalein tablets have been designed for the use of children, and therefore the medicament has been pleasantly flavoured, and the mixture is slightly sweet as compared with a tasteless substance. Phenolphthalein appears to be a very satisfactory laxative in a considerable number of cases.

ROCLA NATURAL TONIC WATER.

THE NATURAL ROCLA TONIC WATER. LONDON OFFICE: 69, EDGWARE-ROAD, MARBLE ARCH, LONDON, W.)

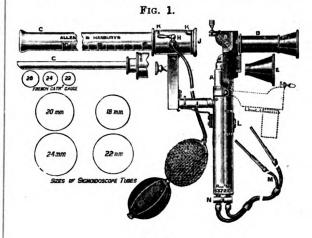

The composition of this water is interesting but not unique. In volcanic districts it is common enough to meet with water impregnated with iron with traces of other metals, including arsenic, derived from beds of iron pyrites. When the water is fresh the iron exists in the form of the soluble protosulphate. After a time it oxidises and the persulphate is then present. That at all events was the condition of the iron in a sample of Rocla water submitted to us. Traces of copper and arsenic were also detected. No doubt in some cases the water supplies the place of a hæmatinic-in, for example, anæmia and general debility, but as a rule a mineral salt of iron, and especially the persulphate, is badly borne, leading to digestive disturbance. The water has a strong astringent action. According to our analysis it contains in solution iron equivalent to 4.48 grammes of ferric oxide per litre. It was chiefly combined in the form of persulphate, the amount of SO3 found being 8.20 grammes per litre. The presence of arsenic in small quantities is calculated to assist the therapeutic action of the iron.

THE ROYAL SANITARY INSTITUTE.—A meeting will be held on Nov. 20th, at 10.30 A.M., in the Council Chamber, Exchange Buildings, Nottingham, when a discussion will take place on the Improvement of City Slums by Housing Reform and Otherwise. The discussion will be opened by Alderman T. J. Dabell, J.P., M.R.C.S., chairman of the health committee, Nottingham. The chair will be taken at health committee, Nottingham. The chair will be taken at 10.30 A.M. by Mr. H. D. Searles-Wood, F.R. I. B. A., chairman of the Council of the Institute. A general discussion is invited. Visits will be made to parts of Radford, Sneinton, and Meadows districts, where reforms are in progress or have been carried out.

Rew Inbentions.

A UNIVERSAL ELECTRICAL ILLUMINATOR.

Messrs. Allen and Hanburys, Limited, of 48, Wigmorestreet, London, W., have constructed to my design a universal electrical illuminator which I have been using for nearly 12 months in conjunction with instruments for the examination of the sigmoid colon, rectum, urethra, &c. The accompanying illustrations (Figs. 1 and 2) convey a very good impression of the general arrangement of the apparatus. Until the recent introduction of the miniature triple filament lamp most of the light rays produced by the electric lamps commonly fitted to endoscopic tubes were reflected on to the walls of the tubes which resulted in a very feeble illumination. To obviate this disadvantage it was found necessary to produce the light at the distal end of the cannula by means of a metal stem to which was screwed a small lamp. In my apparatus, by means of the new lamp invented by Brüning, most of the light is produced in parallel rays and by means of an improved adjustable condensing lens "A" and a circular, plain, reflecting mirror "B" these rays can be projected in parallel beams, thus affording a most brilliant illumina-tion at the distal end of the cannula "C." The tube-carrier,

which can be adjusted by means of an extension shaft "I," presents two apertures and gives attachment to a three-way stopcock "H," which, in the inflating arrangement adopted, allows the pneumatic pressure to be slowly reduced when necessary, thus obviating any risk of the walls of the bowel telescoping into the metal tube. The proximal aperture takes the glass window "J" which is set at the correct angle to ensure there being no back reflection of the light rays. This window is removeable, being attached by a bayonet joint. The distal aperture receives the sigmoidoscopic or urethroscopic tubes, which are all interchangeable and are also fixed by a bayonet joint. four shown in Fig. 1 for examination of the sigmoid

colon are 30 centimetres in length and of 18, 20, 22, and 24 millimetres in diameter. Those illustrated for examination of the urethra are Nos. 22, 24, and 26 French catheter gauge. Obturators for the introduction of these tubes are provided. Fig 2 depicts the method of lateral adjustment, "FG," which enables the lamp to be swung over to the right or left side as desired, for obtaining instantaneously an unobstructed field for cleansing purposes. A telescope, "D," fitted with a sliding eye-piece, giving a magnification of about ten times and a range of from 6 to 18 inches, is adjustable to the apparatus. When magnification is not required a plain funnel-shaped eye-piece "E" is employed. The switch "L" enables the current to be cut off when possible, thus lengthening the life of the lamp and at the same time preventing it from becoming unpleasantly hot. The triple filament lamps require from 10 to 12 volts and they can be illuminated either from a 6-cell accumulator or from a wall rheostat when the main electric current is available. Messrs. Allen and Hanburys supply a small unspillable accumulator known as the "Oslite" which is very suitable for use with this apparatus. The connecting cables "M" are well insulated and are covered with india ubber tubing. Socket terminals are also provided which fit securely on to the pins on the main handle "N."

In this apparatus the following advantages will be at once apparent: 1. There is no obstruction in the lumen of the cannula to interfere with the operator's view. 2. The small lamp used at the distal end of other forms of endoscopic tubes is very liable to fuse or become covered with fæces, mucus, &c., and thus rendered useless. In this instrument these defects are overcome. 3. When it becomes necessary to cleanse the bowel or urethra the lateral adjustment readily enables this to be done, whereas when the light is obtained at the terminal extremity of the tube the lamp has to be constantly withdrawn before this can be accomplished. 4. Finally, the illumination is better than that obtained with any other instrument.

E. Canny Ryall.

Harley-street, W.

ASYLUM REPORTS.

Lamark District Asylum (Report for the year 1908-1909).—The average daily number resident at this asylum during the year ending May 31st was 933. The admissions numbered 269, and show an increase of 21 on those of the previous year, and 39 more than the average admission rate for the last 13 years. The discharges numbered 252. The recovery-rate was 40·3 per cent. on the certified admissions. 30 patients recovered within 3 months of admission, 27 within 6 months, 23 within 12 months, 17 after a residence of from 1 to 4 years, and 3 after a residence of from 1 to 4 years, and 3 after a residence of from 1 to 4 years, and 3 after a residence of from 7 to 11 years. The death-rate was 7·7 per cent. on the average number resident. The medical superintendent, Dr. Neil T. Kerr, points out that of a total of 85 cases of general paralysis admitted to the asylum since its opening 75 patients were males and 10 females, giving a percentage of 88·23 and 11·76 respectively. This is somewhat in excess of the 5 to 1 ratio given by most writers, and serves to bring out even more clearly the greater liability of males to the disease.

Glasgow Mental Hospital, Gartloch (Report for the Year 1908-1909). - During the year ending May 15th, 1909, there were 1033 cases under care. There were admitted 282 patients. There were 106 persons discharged as recovered, this giving a recovery-rate of 37.58 per cent. There were 96 deaths, giving a percentage on the average number resident of 12.6. The male death-rate was 16.3 and is accounted for by the character of the admissions, serious bodily illness being a prominent feature in the majority of the cases admitted. Of the 66 male deaths 27 occurred within six months of admission, and of 282 admissions only 44 are noted as in good bodily health and condition on admission. Dr. W. A. Parker, the medical super-intendent, reports that this year, as usual, alcohol, alone er in combination, was the most prolific determining cause of insanity in the patients admitted. Besides this direct influence it would appear that alcoholism is as notable a feature as ever among the parents of those patients whose breakdown or arrest of mental growth has taken place during the period of most rapid development. So far as treatment of patients is concerned it would appear that open-

air bed treatment continues to give satisfaction and is used in all new and recurrent cases. It secures its best results "in combination with very carefully graded and, as far as possible, purin-free diets." Dr. Parker is of opinion, after an experience of ten years, that the method secures more restfulness, better sleep, and better assimilation of food than when patients are treated either without bed treatment or in bed indoors. In prolonged cases of bed treatment it is combined with massage or hot and cold sprays, prolonged baths, or the static brush applications, to secure peripheral stimulation and improve the circulation and assimilation. The most notable new method of treatment introduced at this asylum during the period in question is musical drill. It promises to be useful in rousing and raising the younger lethargic dements to more useful and active life.

The Queensland Asylums.—The report of the inspector of hospitals for the insane in Queensland shows that on Dec. 31st, 1908, there were 2189 persons suffering from insanity under State control, 1358 being males and 831 being females. The population of the State at the end of 1908 was estimated at 558,237, comprising 308,837 males and 254,400 females. Calculated on these figures, the proportion of insane under care per 1000 of the population was 3.92—4.46 in the case of males and 3.22 in the case of females, this being a slightly higher proportion than in 1907. The distribution of patients in the various hospitals was 1250 at Goodna, 201 at Ipswich, and 733 at Toowoomba, with 5 in the reception-houses at Brisbane, Rockhampton, and Townsville. The average daily number resident was 2120, including 1311 males and 809 females. During 1908 there were 360 cases admitted, of whom 329 were admitted for the first time and 31 had been previously under treatment. Among these 360 admissions there were 155 persons born in Australia and 166 born in Great Britain. There were 112 deaths during the year, the death-rate calculated on the average daily number resident in the hospitals being 5.28 per cent., as against 6.38 per cent. in 1907. During the year the insanity epartment sustained a severe loss in the death of Mr. James Ballantine Hogg, inspector of asylums and medical superintendent of the Hospital for the Insane at Goodna. A peculiarly melancholy event was the fate of Dr. R. R. Whishaw, assistant medical superintendent of the Hospital for the Insane at Toowoomba, who met his death at the hands of a patient.

LONDON COUNTY COUNCIL: COMPENSATION FOR TUBERCULOUS COWS .- A discussion arose at the meeting of the London County Council on Nov. 2nd with regard to the administration of the London County Council (General Powers) Act, 1904, authorising the seizure of cows suffering from tuberculosis of the udder. The public health committee had reported that four cows had recently been seized and slaughtered and sums varying from £11 to £13, being three-fourths of the declared value, had been paid as compensation. Mr. Reynolds, commenting on this, suggested that in recent years an illicit business had grown up for the disposal of tuberculous cattle. The medical officer of health of Portsmouth recently directed attention to "the menace to health through the systematic trade in diseased animals, particularly in tuberculous cows, carried on in markets outside Portsmouth," and stated that owing to active measures taken by the town "the diseased animals are sent to other places, and principally to London." Mr. Reynolds also thought that the London County Council was paying excessive amounts in compensation and that dealers were likely to send their diseased cattle to the metropolis for London ratepayers to pay for. He would like to get at the previous history of such cows. Mr. Easton retorted that, in the absence of general legislation for regulating the milk trade, the history of a particular cow was the very thing that could not be traced. Mr. Gilbert Johnstone, chairman of the public health committee, said that the question of tuberculous cows gravitating to London as a result of the Council's Milk Act had not been overlooked. In passing, he mentioned that the report of the medical officer of health of Portsmouth was written at least a year before their Bill came into force. Since March last only 22 cows had been seized in London. There was no reason to believe that a considerable number of tuberculous cows were being sent to them, but the officials had instructions to report at once if they noted an unusual influx, and in all cases they ascertained how long a cow had been in possession of its present owner.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 13, 1909.

Ourselves.

WE announce to-day on p. 1470 A that THE LANCET at the beginning of the new year will revert to the original price While saying this much about ourselves we are betrayed into a few words on the development of the paper during its 86 years of life. When THE LANCET was born on Sunday, October 5th, 1823, it consisted of 36 small octavo pages, the contents of which were mainly written, with the cooperation of one clerk, by one London surgeon. The measure we give is very different now to that to which the founder of the journal thought his readers entitled. For the past 15 years an average number of THE LANCET has consisted of 160 pages, and the number of subjects with which we are compelled to deal, no less than the world-wide range of addresses from which our foreign correspondents date their communications, show sufficiently that our collaborators make in themselves quite a large reading public. We lay no stress on the inevitable and progressing increase in the size of THE LANCET, for there is not a single successful newspaper with a long history behind it that cannot tell something the same story—it is in the nature of a newspaper that is alive to go on growing. But we are proud of the consistent nature of our work, and of the public confidence that year by year is put in us, while we attempt to act as a medium of interchange between the members of the medical profession in all their scientific and professional relations, and to uphold in all its phases and without fear the cause of medicine. The alteration in the price of THE LANCET has been made in accordance with the intention of the late Mr. THOMAS WAKLEY, junior, who for so many years was joint-editor with his father, and whose untimely death we are still lamenting in common with his many friends.

Hospital Construction.

AT a period of rapid development in any art or science it is always well, and may often be instructive, to pause for the purpose of comparing the present with the past. Less than half a century has elapsed since the late Sir James Simpson, in view of the frightful mortality which then followed surgical operations, advocated the employment, for hospital purposes, of temporary buildings, which could be destroyed by fire as soon as they became sufficiently saturated with noxious emanations to be sources of danger to those who were treated in them. It is perhaps a little humiliating to remember that this counsel was given at a time when the discoveries of LISTER had already dawned upon the world, and that the brilliant obstetrician was unable to foresee the extent to which these discoveries would overcome the

evils which he deplored, and would obviate the necessity for the destructive expedients which he advocated. The complete establishment of the principles and practice of aseptic surgery appeared for a time to sanction the belief that hospitals might safely be constructed in such a manner as to bestow upon them a character of permanence, in so far, at least, as that character can be attached to the work of human hands; and it is only now that we are beginning to realise that structures are prone to become obsolete, and that the growing requirements of medical and surgical practice can only be completely satisfied in the presence of a vast number of architectural and other facilities for which no adequate provision has until quite recently anywhere been made, which are conspicuously absent from many buildings to which the name and character of a "hospital" are attached, and which are used for the reception and treatment of patients. No one can venture to dispute that the ideal construction of to-day may before long be found to fall short of the increasing requirements likely to arise from increasing knowledge, and hence to be superseded in its turn; but the present character of that ideal construction is admirably set forth in a recent publication by which these remarks have in the main been suggested. Dr. DONALD J. MACKINTOSH, M.V.O., medical superintendent of the Western Infirmary, Glasgow, has written a treatise on the construction, equipment, and management of a general hospital 1 which seems practically to exhaust the subjects with which it deals, and which is calculated not only to serve as a handbook for architects engaged in hospital design, but also as a guide of considerable practical utility for all who are afterwards engaged in the application of the building and its accessories to their proper and destined uses. No staff or committee bent upon the erection of a new hospital or upon the improvement of an old one can safely neglect the principles and details which Dr. MACKINTOSH has laid down.

It would be somewhat beyond our present limits to enter into any detailed discussion of the various elements of hospital construction and administration which Dr. MAC-KINTOSH has lucidly placed before his readers, and which he has illustrated by a profusion of plans and drawings, but they include the gatehouse or admission block of the hospital. the ward unit, whether medical, surgical, or special, the out-patient department, the kitchen and laundry, provision for nervous diseases or for cases of incipient insanity, the general heating arrangements, and the requirements of the nurses' home. The nursing and ward-maids staff for each unit and the accommodation for them, and the resident medical officer for each unit and his proper location with regard to it, are also considered. The operating theatres receive special attention, both as regards construction and equipment, and no detail is too small to be fully noticed in its appropriate place. The photographic illustrations of wards and other interiors are, we presume, taken from the hospital which is under Dr. MACKINTOSH's immediate charge, and to the governing body of which, in his preface, he pays what is manifestly a well-deserved tribute for "the unfailing encouragement which they have given to every scheme calculated to promote the welfare of the patients,"

and to whose progressive spirit and zeal for efficiency he acknowledges his indebtedness for the facilities which he has had for acquiring knowledge of the best materials and methods of construction. The book is completed by a series of appendices dealing with various subjects related to its main purpose, such as with the requirements in the way of apparatus, instruments, linen, cutlery, crockery, and so forth, for a ward unit of specified size; an "analysis" of the arrangements for nurses at the Toronto Hospital for Sick Children, which are described as being of especial excellence; and an account of the conditions of medical and surgical appointments and of nursing service in the principal hospitals of the United Kingdom. It is, in fact, little less than an encyclopædia of hospital construction and management, and deals with every related subject except the actual treatment of the patients. The forms for books and registers and the suggestions for inquiries touching the means of applicants for relief, appear to be specially worthy of attention.

But in striving to realise by the mental vision the picture of a perfect and perfectly equipped hospital which Dr. MACKINTOSH has drawn for our instruction, we have more than once been led to question the position to which it would be entitled as an educational instrument. A young medical man entering upon practice is called upon to treat patients in a variety of circumstances, many of them extremely adverse to health; and, if he has been taught his profession under the highly artificial conditions described by Dr. MACKINTOSH, it would scarcely be a matter for surprise if he were unable to adapt himself to more ordinary ones, and if he were to fail in doing the best that was possible in the cottage of the workman, or even in the ordinary residences of middle-class people. It is obvious that the aggregation of patients in a single building involves risks which hardly present themselves in the case of one sick person in a private house; but the conditions of the private house are constantly and in high degrees unfavourable, and they have regularly to be encountered and overcome in practice. We greatly question whether the conditions of the pattern hospital would not have some tendency to disqualify the student who had been trained among them; they might be to him somewhat of the nature of leading strings, or of corks or bladders to one who was learning to swim. Such conditions protect both the learner and the patients in hospital against dangers from which in private practice he would have to find, and often to extemporise, methods of protection for We are here reminded of an old exahimself. mination story about two students who were respectively asked to deal with a foreign body in the auditory meatus of a cadaver. One of them asked to be supplied with the aural speculum, the methods of illumination, and the pattern of forceps which had been designed by the lecturer upon aural surgery at the school at which he had been taught. The other picked up a bit of wire that was lying at hand, twisted it into a snare, and removed the offending substance in a moment. The better the hospital, and the more complete its appliances at which the student has been educated, the more necessary will it become

conveniences upon the presence of which he must not reckon elsewhere, and the more important it is that he should be taught the principles of asepticism and the possibilities of securing it under externally adverse conditions. We cordially sympathise with the view that the hospitals should afford every possible security and advantage to all who are treated in them; but we also feel that the students should be rendered, as far as possible, independent of institutional facilities, and should be taught to consider how the absence of these facilities should be encountered in the private house and in the conditions of daily life. In the metropolis and in other great cities provision more or less analogous to that afforded by hospitals is furnished by nursing homes and other arrangements; but in rural districts the practitioner is constantly called upon to be his own sanitary officer, and it is of the first importance to his success that he should have been effectively trained in this department of his work.

The Therapeutics of Suggestion.

THE history of the medical profession, amidst much that is encouraging to the men of our own day, discloses also that which is disappointing and calculated to make us pause as we discourse on the progress of science in general and of our art in particular. Of therapeutics this is more especially the case. The practitioner of a generation or two back, as he left the schools, was in the first place a therapist and only very secondarily a pathologist and diagnostician. To-day he is better able to discover the site of a disease and to classify it when found, but he has exchanged the therapeutic confidence of his forbears in medicine for a scepticism which is sometimes paralysing to his efforts. For centuries civilised communities bore, as Sir John Forbes wrote in 1857, "the evils of polypharmacy and of that meddlesome and perturbative practice" which was still so prevalent in his day. Polypharmacy still prevails, but at its side take rank methods which at their introduction were vaunted as opening up more certain roads to health. Hydrotherapy, Mechano-Therapeutics, Hypnotism, Therapy in connexion with the coal-tar products, with many another method of more recent date, have been announced to the world in terms of the warmest commendation, have been as warmly denounced as futile or even dangerous, and with the lapse of time have found a place in our armamentarium which is neither particularly base nor particularly distinguished.

one who had been associated with this Journal for nearly 40 years wrote in 1874: "There is no chapter in the history of medicine more astounding and bewildering than the episode of 1837-38, when for a time animal magnetism or mesmerism engrossed the attention of the profession and the public." In a lecture delivered by Dr. Elliotson in August, ition, and the pattern of forceps which had been designed by the lecturer upon aural surgery at the school at which he had been taught. The other picked up a bit of wire that was lying at hand, twisted it into a snare, and removed the offending substance in a moment. The better the hospital, and the more complete its appliances at which the student has been educated, the more necessary will it become that he should learn to regard these appliances as artificial

scientific inquiry difficult. In the public discussion of the subject invective and vituperation worthy of a political platform formed the chief weapons of the respective sides, and ultimately Dr. Elliotson, as a result of a resolution passed by the Council of University College to the effect "that the hospital committee be instructed to take such steps as they shall deem most advisable to prevent the practice of mesmerism or animal magnetism in future within the hospital," resigned his position as physician to the hospital. From this time mesmerism ceased seriously to exercise the minds of members of the profession in this country. It is true that BRAID, working in 1841 and for long after, suggested the term hypnotism and gave to the world admirable accounts of the phenomena of that condition, but it was left to foreign scientists to elaborate his work and to speculate as to the physiological or pathological foundations of the states observed. Dr. G. H. SAVAGE, in the Harveian Oration for this year, selected hypnotism as the central theme of his oration, not, as it would appear, altogether without misgiving as to its dangerous character. The subject has, doubtless, a sinister connotation both for the public at large and for the medical profession in particular. The word carries suggestions of the public platform and of a disgraceful charlatanism which holds its loathsome exhibitions to satisfy a morbid and ignorant curiosity. There is no more justification for the platform performance of hypnotism than for the platform performance of surgical operations. Exhibitions of this character are alike degrading to the hypnotiser, the hypnotised, and the public who witness them; nor is the induction of hypnotism likely to be without mental harm to the unfortunates who for a few shillings submit themselves to useless and unskilled experimentation. Hypnotism as a therapeutic agent of value is no new thing. It has been used for years on the Continent in the judicial school of CHARCOT, his associates and followers. It has passed through a stage of exuberantly enthusiastic support, through a stage of chilling criticism, and at length occupies a fairly defined place. It is not a panacea. It is useful here and useless there. As with most remedies which have not been mere fashions of the passing hour, it may produce sometimes results which are little less than miraculous and at others results which are positively harmful, and it is for the physician, as a man of science, carefully to select the cases which may be benefited, and not, as the charlatan, indiscriminately to dose all his patients with the same medicament.

Obsely following upon the Harveian Oration a discussion took place at a meeting of the Harveian Society upon "suggestion" in the treatment of morbid conditions. In the continental school, which has in the past practised hypnotism very extensively, there has grown up an opinion that while suggestion, used either with or without the induction of the hypnotic trance, is of considerable value, there yet remains a simple method which is its superior and which seeks to produce its results with the help of persuasion. No part of the nationt's personality is suppressed or placed in abeyance, but an appeal is made to the crowning function of all the functions—namely, to the mind. By careful methods of rational persuasion and with the active cooperation of the
